Introduction

The purpose of these notes is to explore some simple relations between Markovian path and loop measures, the Poissonian ensembles of loops they determine, their occupation fields, uniform spanning trees, determinants, and Gaussian Markov fields such as the free field. These relations are first studied in complete generality in the finite discrete setting, then partly generalized to specific examples in infinite and continuous spaces.

These notes contain the results published in [29] where the main emphasis was put on the study of occupation fields defined by Poissonian ensembles of Markov loops. These were defined in [20] for planar Brownian motion in relation with SLE processes and in [21] for simple random walks. They appeared informally already in [54]. For half integral values $\frac{k}{2}$ of the intensity parameter $\alpha$, these occupation fields can be identified with the sum of squares of $k$ copies of the associated free field (i.e. the Gaussian field whose covariance is given by the Green function). This is related to Dynkin’s isomorphism (cf [8], [35], [25]).

As in [29], we first present the theory in the elementary framework of symmetric Markov chains on a finite space. After some generalities on graphs and symmetric Markov chains, we study the $\sigma$-finite loop measure associated to a field of conductances. Then we study geodesic loops with an exposition of results of independent interest, such as the calculation of Ihara’s zeta function. After that, we turn our attention to the Poisson process of loops and its occupation field, proving also several other interesting results such as the relation between loop ensembles and spanning trees given by Wilson algorithm and the reflection positivity property. Spanning trees are related to the fermionic Fock space as Markovian loop ensembles are related to the bosonic Fock space, represented by the free field. We also study the decompositions of the loop ensemble induced by the excursions into the complement of any given set.
Then we show that some results can be extended to more general Markov processes defined on continuous spaces. There are no essential difficulties for the occupation field when points are not polar but other cases are more problematic. As for the square of the free field, cases for which the Green function is Hilbert Schmidt such as those corresponding to two and three dimensional Brownian motion can be dealt with through appropriate renormalization.

We show that the renormalized powers of the occupation field (i.e. the self intersection local times of the loop ensemble) converge in the case of the two dimensional Brownian motion and that they can be identified with higher even Wick powers of the free field when $\alpha$ is a half integer.

At first, we suggest the reader could omit a few sections which are not essential for the understanding of the main results. These are essentially some of the generalities on graphs, results about wreath products, infinite discrete graphs, boundaries, zeta functions, geodesics and geodesic loops. The section on reflexion positivity, and, to a lesser extent, the one on decompositions are not central. The last section on continuous spaces is not written in full detail and may seem difficult to the least experienced readers.

These notes include those of the lecture I gave in St Flour in July 2008 with some additional material. I choose this opportunity to express my thanks to Jean Picard, to the audience and to the readers of the preliminary versions whose suggestions were very useful, in particular to Juergen Angst, Cedric Bordenave, Cedric Boutiller, Jinshan Chang, Antoine Dahlqvist, Thomas Duquesne, Michel Emery, Jacques Franchi, Hatem Hajri, Liza Jones, Adrien Kassel, Rick Kenyon, Sophie Lemaire, Thierry Levy, Titus Lupu, Gregorio Moreno, Jay Rosen (who pointed out a mistake in the expression of renormalization polynomials), Bruno Shapira, Alain Sznitman, Vincent Vigon, Lorenzo Zambotti and Jean Claude Zambrini.
Chapter 1
Symmetric Markov processes on finite spaces

Notations: functions and measures on finite (or countable) spaces are often denoted as vectors and covectors, i.e. with upper and lower indices, respectively.

The multiplication operator defined by a function $f$ acting on functions or on measures is in general simply denoted by $f$, but sometimes, to avoid confusion, it will be denoted by $M_f$. The function obtained as the density of a measure $\mu$ with respect to some other measure $\nu$ is simply denoted $\mu_\nu$.

1.1 Graphs

Our basic object will be a finite space $X$ and a set of non negative conductances $C_{x,y} = C_{y,x}$, indexed by pairs of distinct points of $X$. This situation allows to define a kind of discrete topology and geometry. In this first section, we will briefly study the topological aspects.

We say that $\{x, y\}$, for $x \neq y$ belonging to $X$, is a link or an edge iff $C_{x,y} > 0$. An oriented edge $(x,y)$ is defined by the choice of an ordering in an edge. We set $-(x, y) = (y, x)$ and if $e = (x, y)$, we denote it also $(e^-, e^+)$. The degree $d_x$ of a vertex $x$ is by definition the number of edges incident at $x$.

The points of $X$ together with the set of non oriented edges $E$ define a graph $(X, E)$. We assume it is connected. The set of oriented edges is denoted $E^o$. It will always be viewed as a subset of $X^2$, without reference to any imbedding.

The associated line graph is the oriented graph defined by $E^o$ as set of vertices and in which oriented edges are pairs $(e_1, e_2)$ such that $e_1^+ = e_2^-$. The mapping $e \rightarrow -e$ is an involution of the line graph.
An important example is the case in which conductances are equal to zero or one. Then the conductance matrix is the adjacency matrix of the graph:
\[ C_{x,y} = 1_{\{x,y\} \in E} \]
A complete graph is defined by all conductances equal to one.

The complete graph with \( n \) vertices is denoted \( K_n \). The complete graph \( K_4 \) is the graph defined by the tetrahedron. \( K_5 \) is not planar (i.e. cannot be imbedded in a plane), but \( K_4 \) is.

![Complete graphs](image)

**Fig. 1.1** Complete graphs

A finite discrete path on \( X \), say \( (x_0, x_1, ..., x_n) \) is called a (discrete) geodesic arc iff \( \{x_i, x_{i+1}\} \in E \) (path segment on the graph) and \( x_{i-1} \neq x_{i+1} \) (without backtraking). Geodesic arcs starting at \( x_0 \) form a marked tree \( \mathcal{T}_{x_0} \) rooted in \( x_0 \) (the marks belong to \( X \); they are the endpoints of the geodesic arcs).

Oriented edges of \( \mathcal{T}_{x_0} \) are defined by pairs of geodesic arcs of the form:
\[ ((x_0, x_1, ..., x_n), (x_0, x_1, ..., x_n, x_{n+1})) \]
(the orientation is defined in reference to the root). \( \mathcal{T}_{x_0} \) is a universal cover of \( X \) [36].

A (discrete) loop based at \( x_0 \in X \) is by definition a path \( \xi = (\xi_1, ..., \xi_p(\xi)) \), with \( \xi_1 = x_0 \), and \( \{\xi_i, \xi_{i+1}\} \in E \), for all \( 1 \leq i \leq p \) with the convention \( \xi_{p+1} = \xi_1 \). On the space \( \mathcal{L}_{x_0} \) of discrete loops based at some point \( x_0 \), we can define an operation of concatenation, which provides a monoid structure, i.e. is associative with a neutral element (the empty loop). The concatenation of two closed geodesics (i.e. geodesic loops) based at \( x_0 \) is not directly a closed geodesic. It can involve backtraking ”in the middle” but then after cancellation of the two inverse subarcs, we get a closed geodesic, possibly empty if the two closed geodesics are identical up to reverse order. With this operation, closed geodesics based at \( x_0 \) define a group \( \Gamma_{x_0} \). The structure of \( \Gamma_{x_0} \) does not depend on the base point and defines the fundamental group \( \Gamma \) of the graph (as the graph is connected: see for example [36]). Indeed, any geodesic arc \( \gamma_1 \) from \( x_0 \) to another point \( y_0 \) of \( X \) defines an isomorphism between \( \Gamma_{x_0} \) and \( \Gamma_{y_0} \). It associates to a closed geodesic \( \gamma \) based in \( x_0 \) the...
closed geodesic $[\gamma_1]^{-1}\gamma_1$ (here $[\gamma_1]^{-1}$ denotes the backward arc). In the case where $x_0 = y_0$, it is an interior isomorphism (conjugation by $\gamma_1$).

There is a natural left action of $\Gamma_{x_0}$ on $\mathcal{T}_{x_0}$. It can be interpreted as a change of root in the tree (with the same mark). Besides, any geodesic arc between $x_0$ and another point $y_0$ of $X$ defines an isomorphism between $\mathcal{T}_{x_0}$ and $\mathcal{T}_{y_0}$ (change of root, with different marks).

We have just seen that the universal covering of the finite graph $(X,E)$ at $x_0$ is a tree $\mathcal{T}_{x_0}$ projecting on $X$. The fiber at $x_0$ is $\Gamma_{x_0}$. The groups $\Gamma_{x_0}, x_0 \in X$ are conjugated in a non canonical way. Note that $X = \Gamma_{x_0}\backslash\mathcal{T}_{x_0}$ (here the use of the quotient on the left corresponds to the left action).

**Example 1.** Among graphs, the simplest ones are $r$–regular graphs, in which each point has $r$ neighbours. A universal covering of any $r$–regular graph is isomorphic to the $r$–regular tree $\mathcal{T}^{(r)}$.

**Example 2.** Cayley graphs: a finite group with a set of generators $S = \{g_1, \ldots, g_k\}$ such that $S \cap S^{-1}$ is empty defines an oriented $2k$-regular graph.

A spanning tree $T$ is by definition a subgraph of $(X,E)$ which is a tree and covers all points in $X$. It has necessarily $|X| - 1$ edges, see for example two spanning trees of $K_4$.

The inverse images of a spanning tree by the canonical projection from a universal cover $\mathcal{T}_{x_0}$ onto $X$ form a tesselation on $\mathcal{T}_{x_0}$, i.e. a partition of $\mathcal{T}_{x_0}$ in identical subtrees, which are fundamental domains for the action of $\Gamma_{x_0}$. Conversely, a section of the canonical projection from the universal cover defines a spanning tree.

Fixing a spanning tree determines a unique geodesic between two points of $X$. Therefore, it determines the conjugation isomorphisms between the various groups $\Gamma_{x_0}$ and the isomorphisms between the universal covers $\mathcal{T}_{x_0}$.

![Fig. 1.2 Two spanning trees of $K_4$](image-url)
Remark 1. Equivalently, we could have started with an infinite tree $\mathcal{T}$ and a group $\Gamma$ of isomorphisms of this tree such that the quotient graph $\Gamma \setminus \mathcal{T}$ is finite.

The fundamental group $\Gamma$ is a free group with $|E| - |X| + 1 = r$ generators. To construct a set of generators, one considers a spanning tree $T$ of the graph, and choose an orientation on each of the $r$ remaining links. This defines $r$ oriented cycles on the graph and a system of $r$ generators for the fundamental group. (See [36] or Serres ([43]) in a more general context).

Here is a picture of the universal covering of $K_4$, and of the action of the fundamental group with the tesselation defined by a spanning tree.

Fig. 1.3 Universal cover and tesselation of $K_4$

There are various non-ramified coverings, intermediate between $(X, E)$ and the universal covering. Non ramified means that locally, the covering space is identical to the graph (same incident edges). Then each oriented path segment on $X$ can be lifted to the covering in a unique way, given a lift of its starting point.
Each non ramified covering is (up to an isomorphism) associated with a subgroup \( H \) of \( \Gamma \), defined up to conjugation. More precisely, given a non ramified covering \( \tilde{X} \), a point \( x_0 \) of \( X \) and a point \( \tilde{x}_0 \) in the fiber above \( x_0 \), the closed geodesics based at \( x_0 \) whose lift to the covering starting at \( \tilde{x}_0 \) are closed form a subgroup \( H_{\tilde{x}_0} \) of \( \Gamma_{x_0} \), canonically isomorphic to the fundamental group of \( \tilde{X} \) represented by closed geodesics based at \( \tilde{x}_0 \). If we consider a different point \( \tilde{y}_0 \), any geodesic path segment \( \tilde{\gamma}_1 \) between \( \tilde{x}_0 \) and \( \tilde{y}_0 \) defines an isomorphism between \( \Gamma_{x_0} \) and \( \Gamma_{y_0} \) which exchanges \( H_{\tilde{x}_0} \) and \( H_{\tilde{y}_0} \).

Denoting \( \gamma_1 \) the projection of \( \tilde{\gamma}_1 \) on \( X \), it associates to a closed geodesic \( \gamma \) based in \( x_0 \) whose lift to the covering is closed the closed geodesic \( \gamma_1^{-1} \gamma \gamma_1 \) whose lift to the covering is also closed.

**Example 4.** By central symmetry, the cube is a two fold covering of the tetrahedron associated with the group \( \mathbb{Z}/2\mathbb{Z} \).

Conversely, if \( H \) is a subgroup of \( \Gamma_{x_0} \), the covering is defined as the quotient graph \((Y,F)\) with \( Y = H \backslash \tilde{X}_{x_0} \) and \( F \) the set of edges defined by the canonical projection from \( \tilde{X}_{x_0} \) onto \( Y \). \( H \) can be interpreted as the group of closed geodesics on the quotient graph, based at \( H_{x_0} \), i.e. as the fundamental group of \( Y \).

If \( H \) is a normal subgroup, the quotient group (also called the covering group) \( H \backslash \Gamma_{x_0} \) acts faithfully on the fiber at \( x_0 \). An example is the commutator subgroup \([\Gamma_{x_0}, \Gamma_{x_0}]\). The associate covering is the maximal Abelian covering at \( x_0 \).

**Exercise 1.** Determine the maximal Abelian cover of the tetrahedron.

### 1.2 Energy

Let us consider a nonnegative function \( \kappa \) on \( X \). Set \( \lambda_x = \kappa_x + \sum_y C_{x,y} \) and \( P^x_y = \frac{C_{x,y}}{\lambda_x} \). \( P \) is a (sub) stochastic transition matrix which is \( \lambda \)-symmetric (i.e. such that \( \lambda_x P^x_y = \lambda_y P^y_x \)) with \( P^x_x = 0 \) for all \( x \) in \( X \).

It defines a symmetric irreducible Markov chain \( \xi_n \).

We can define above it a continuous time \( \lambda \)-symmetric irreducible Markov chain \( x_t \), with exponential holding times of parameter 1. We have \( x_t = \xi_{N_t} \), where \( N_t \) denotes a Poisson process of intensity 1. The *infinitesimal generator* is given by \( L^x_y = P^x_y - \delta^x_y \).

We denote by \( P_t \) its (sub) Markovian semigroup \( \exp(Lt) = \sum k! \frac{L^k}{k!} \). \( L \) and \( P_t \) are \( \lambda \)-symmetric.

We will use the Markov chain associated with \( C, \kappa \), sometimes in discrete time, sometimes in continuous time (with exponential holding times).
Recall that for any complex function $z, x \in X$, the “energy”

$$e(z) = \langle -Lz, \overline{z} \rangle_{\lambda} = \sum_{x \in X} - (Lz)^x \overline{z}^x \lambda_x$$

is nonnegative as it can be easily written

$$e(z) = \sum_x \lambda_x z^x \overline{z}^x - \sum_{x,y} C_{x,y} z^x \overline{z}^y = \frac{1}{2} \sum_{x,y} C_{x,y} (z^x - z^y)(\overline{z}^x - \overline{z}^y) + \sum_x \kappa_x z^x \overline{z}^x$$

The Dirichlet space ([12]) is the space of real functions equipped with the energy scalar product

$$e(f, g) = \frac{1}{2} \sum_{x,y} C_{x,y} (f^x - f^y)(g^x - g^y) + \sum_x \kappa_x f^x g^x = \sum_x \lambda_x f^x \overline{g}^x - \sum_{x,y} C_{x,y} f^x g^y$$

defined by polarization of $e$.

Note that the non negative symmetric "conductance matrix" $C$ and the non negative equilibrium or "killing" measure $\kappa$ are the free parameters of the model.

**Exercise 2.** Prove that the eigenfunction associated with the lowest eigenvalue of $-L$ is unique and has constant sign by an argument based on the fact that the map $z \to |z|$ lowers the energy (which follows easily from the expression given above).

In quantum mechanics, the infinitesimal generator $-L$ is called the Hamiltonian and its eigenvalues are the energy levels.

One can learn more on graphs and eigenvalues in [2].

We have a dichotomy between:

- the recurrent case where 0 is the lowest eigenvalue of $-L$, and the corresponding eigenspace is formed by constants. Equivalently, $P1 = 1$ and $\kappa$ vanishes.
- the transient case where the lowest eigenvalue is positive which means there is a "Poincaré inequality": For some positive $\varepsilon$, the energy $e(f, f)$ dominates $\varepsilon \langle f, f \rangle_{\lambda}$ for all $f$. Equivalently, as we are on a finite space, $\kappa$ does not vanish. Note however these equivalences do not hold in general on infinite spaces, though the dichotomy is still valid.

In the transient case, we denote by $V$ the associated potential operator $(−L)^{-1} = \int_{0}^{\infty} P_{dt}$. It can be expressed in terms of the spectral resolution of $L$. We will denote $\sum_y V_y f^y$ by $(V f)^x$ or $V f(x)$.

Note that the function $V f$ (called the potential of $f$) is characterized by the identity
\[ e(Vf,g) = \langle f,g \rangle_\lambda \]

valid for all functions \( f \) and \( g \). The potential operator diverges on positive functions in the recurrent case. These properties define the dichotomy transient/recurrent on infinite spaces.

We denote by \( G \) the Green function defined on \( X^2 \) as \( G^{x,y} = \frac{V^{x}_{\lambda_y}}{\lambda_y} = \frac{1}{\lambda_y}[(I - P)^{-1}]_y \) i.e. \( G = (M_\lambda - C)^{-1} \). It induces a linear bijection from measures into functions. We will denote \( \sum_y G^{x,y} \mu_y \) by \((G\mu)^x \) or \( G\mu(x) \).

Note that the function \( G\mu \) (called the potential of \( \mu \)) is characterized by the identity

\[ e(f,G\mu) = \langle f,\mu \rangle \]

valid for all functions \( f \) and measures \( \mu \). In particular \( G\kappa = 1 \) as \( e(1,f) = \sum f^x \kappa_x = \langle f,1 \rangle_\kappa \).

**Example 5.** The Green function in the case of the complete graph \( K_n \) with uniform killing measure of intensity \( c > 0 \) is given by the matrix

\[ \frac{1}{n+c}(I + \frac{1}{c}J) \]

where \( J \) denotes the \((n,n)\) matrix with all entries equal to 1.

**Proof.** Note first that \( M_\lambda - C = (n+c)I - J \). The inverse is easily checked.

See ([12]) for a development of this theory in a more general setting.

In the recurrent case, the potential operator \( V \) can be defined on the space \( \lambda^\perp \) of functions \( f \) such that \( \langle f,1 \rangle_\lambda = 0 \) as the inverse of the restriction of \( I - P \) to \( \lambda^\perp \). The Green operator \( G \) maps the space of measures of total charge zero onto \( \lambda^\perp \): setting for any signed measure \( \nu \) of total charge zero \( G\nu = V^{x}_\kappa \), we have for any function \( f \), \( \langle \nu, f \rangle = e(G\nu,f) \) (as \( e(G\nu,1) = 0 \)) and in particular \( f^x - f^y = e(G(\delta_x - \delta_y),f) \).

**Exercise 3.** In the case of the complete graph \( K_n \), show that the Green operator is given by:

\[ G\nu(x) = \frac{V^{x}_\nu}{n} \]

**Remark 2.** Markov chains with different holding times parameters are associated with the same energy form. If \( q \) is any positive function on \( X \), the Markov chain with \( y_t \) holding times parameter \( q^x \), \( x \in X \) is obtained from \( x_t \) by time change: \( y_t = x_{\sigma_t} \), where \( \sigma_t \) is the right continuous increasing family of stopping times defined by \( \int_0^{\sigma_t} q^{-1}(x_s)ds = t \). Its semigroup is \( q^{-1} \lambda \)-symmetric with infinitesimal generator given by \( qL \). The potential operator
is different but the Green function does not change. In particular, if we set \( q^x = \lambda_x \) for all \( x \), the duality measure is the counting measure and the potential operator \( V \) is given by the Green function \( G \). The associated rescaled Markov chain will be used in the next chapters.

### 1.3 Feynman-Kac formula

A discrete analogue of the Feynman-Kac formula can be given as follows: Let \( s \) be any function on \( X \) taking values in \((0,1]\). Then, for the discrete Markov chain \( \xi_n \) associated with \( P \), it is a straightforward consequence of the Markov property that:

\[
E_x \left( \prod_{j=0}^{n-1} s(\xi_j) 1_{\{\xi_n = y\}} \right) = \left[ (M_n P)^n \right]_y^x
\]

Similarly, for the continuous time Markov chain \( x_t \) (with exponential holding times), we have the Feynman-Kac formula:

**Proposition 1.** If \( k(x) \) is a nonnegative function defined on \( X \),

\[
E_x(e^{-\int_0^t k(x_s)ds} 1_{\{x_t = y\}}) = \exp(t(L - M_k))_y^x.
\]

**Proof.** It is enough to check, by differentiating the first member \( V(t) \) with respect to \( t \), that \( V'(t) = (L - M_k)V(t) \).

Precisely, if we set \((V_t)_y^x = E_x(e^{-\int_0^t k(x_s)ds} 1_{\{x_t = y\}})\), by the Markov property,

\[
(V_{t+\Delta t})_y^x = E_x(e^{-\int_0^t k(x_s)ds}E_{x_t}(e^{-\int_0^{\Delta t} k(x_s)ds} 1_{\{x_{\Delta t} = y\}}))
\]

\[
= \sum_{z \in X} E_x(e^{-\int_0^t k(x_s)ds} 1_{\{x_t = z\}}E_z(e^{-\int_0^{\Delta t} k(x_s)ds} 1_{\{x_{\Delta t} = y\}}))
\]

\[
= \sum_{z \in X} (V_t)_z^y E_z(e^{-\int_0^{\Delta t} k(x_s)ds} 1_{\{x_{\Delta t} = y\}}).
\]

Then one verifies easily by considering the first and second times of jump that as \( \Delta t \) goes to zero, \( E_y(e^{-\int_0^{\Delta t} k(x_s)ds} 1_{\{x_{\Delta t} = y\}}) - 1 \) is equivalent to \(-(k(y) + 1)\Delta t\) and for \( z \neq y \), \( E_z(e^{-\int_0^{\Delta t} k(x_s)ds} 1_{\{x_{\Delta t} = y\}}) \) is equivalent to \( P_y^z \Delta t \).

**Exercise 4.** Verify the last assertion of the proof.

For any nonnegative measure \( \chi \), set \( V_\chi = (-L + M_\chi)^{-1} \) and \( G_\chi = V_\chi^{-1} \). It is a symmetric nonnegative function on \( X \times X \). \( G_0 \) is the Green function \( G \), and \( G_\chi \) can be viewed as the Green function of the energy form \( e_\chi = e + \parallel \parallel L^2(\chi) \).

Note that \( e_\chi \) has the same conductances \( C \) as \( e \), but \( \chi \) is added to the killing measure. Note also that \( V_\chi \) is not the potential of the Markov chain.
associated with $e^{\chi}$ when one takes exponential holding times of parameter 1: the holding time expectation at $x$ becomes $\frac{1}{1+\lambda(x)}$. But the Green function is intrinsic i.e. invariant under a change of time scale. Still, we have by Feynman Kac formula
\[
\int_0^\infty E_x(e^{-\int_0^t \frac{\chi(s_x)}{\lambda(s_x)} ds_1} 1_{x_1=y}) dt = [V_\chi]_{xy}.
\]
We have also the "generalized resolvent equation" $V - V_\chi = VM_\chi V_\chi = V_\chi M_\chi V_\chi$. Then,
\[
G - G_\chi = GM_\chi G_\chi = G_\chi M_\chi G
\]
(1.1)

**Exercise 5.** Prove the generalized resolvent equation.

Note that the recurrent Green operator $G$ defined on signed measures of zero charge is the limit of the transient Green operator $G_\chi$, as $\chi \to 0$.

### 1.4 Recurrent extension of a transient chain

It will be convenient to add a cemetery point $\Delta$ to $X$, and extend $C$, $\lambda$ and $G$ to $X^\Delta = \{X \cup \Delta\}$ by setting, $\lambda_\Delta = \sum_{x \in X} \kappa_x$, $C_{x,\Delta} = \kappa_x$ and $G_{x,\Delta} = G_{\Delta,x} = G_{\Delta,\Delta} = 0$ for all $x \in X$. Note that $\lambda(X^\Delta) = \sum_{x \in X} C_{x,y} + 2 \sum_{x \in X} \kappa_x = \lambda(X) + \lambda_\Delta$.

One can consider the recurrent "resurrected" Markov chain defined by the extensions of the conductances to $X^\Delta$. An energy $e^\Delta$ is defined by the formula
\[
e^\Delta(z) = \frac{1}{2} \sum_{x,y \in X^\Delta} C_{x,y} (z^x - z^y)(z^x - z^y)
\]
From the irreducibility assumption, it follows that $e^\Delta$ vanishes only on constants. We denote by $P^\Delta$ the transition kernel on $X^\Delta$ defined by
\[
[P^\Delta]_{xy} = \frac{C_{x,y}}{\sum_{y \in X^\Delta} C_{x,y}} = \frac{C_{x,y}}{\lambda_x}
\]
Note that $P^\Delta 1 = 1$ so that $\lambda$ is now an invariant measure with $\lambda_x [P^\Delta]_{xy} = \lambda_y [P^\Delta]_{yx}$ on $X^\Delta$. Also
\[
e^\Delta(f,g) = \langle f - P^\Delta f, g \rangle_\lambda
\]
Denote $V^\Delta$ and $G^\Delta$ the associated potential and Green operators.

Note that for $\mu$ carried by $X$, for all $x \in X$, denoting by $e_\Delta$ the unit point mass at $\Delta$,
\[
\mu_x = e^\Delta(G^\Delta(\mu - \mu(X) e_\Delta), 1_x) = \lambda_x((I - P^\Delta)G^\Delta(\mu - \mu(X) e_\Delta))(x)
\]
\[
= \lambda_x((I - P)G^\Delta(\mu - \mu(X) e_\Delta))(x) - \kappa_x G^\Delta(\mu - \mu(X) e_\Delta)(\Delta).
\]
Hence, applying $G$, it follows that on $X^\Delta$,

$$G\mu = G^\Delta(\mu - \mu(X)\varepsilon\Delta) - G^\Delta(\mu - \mu(X)\varepsilon\Delta)(\Delta)G\kappa = G^\Delta(\mu - \mu(X)\varepsilon\Delta) - G^\Delta(\mu - \mu(X)\varepsilon\Delta)(\Delta).$$

Moreover, as $G^\Delta(\mu - \mu(X)\varepsilon\Delta)$ is in $\lambda^\perp$, integrating by $\lambda$, we obtain that

$$\sum_{x \in X} \lambda_x G(\mu) = -G^\Delta(\mu - \mu(X)\varepsilon\Delta)(\Delta)\lambda(X^\Delta).$$

Therefore,

$$G^\Delta(\mu - \mu(X)\varepsilon\Delta)(\Delta) = -\langle \lambda, G\mu \rangle_{\lambda(X^\Delta)}$$

and we get the following:

**Proposition 2.** For any measure $\mu$ on $X$, $G^\Delta(\mu - \mu(X)\varepsilon\Delta) = -\langle \lambda, G\mu \rangle_{\lambda(X^\Delta)} + G\mu$.

This type of extension can be done in a more general context (See [27] and Dellacherie-Meyer [6])

**Remark 3.** Conversely, a recurrent chain can be killed at any point $x_0$ of $X$, defining a Green function $G^{X-\{x_0\}}$ on $X - \{x_0\}$. Then, for any $\mu$ carried by $X - \{x_0\}$,

$$G^{X-\{x_0\}} \mu = G(\mu - \mu(X)\varepsilon_{x_0}) - G(\mu - \mu(X)\varepsilon_{x_0})(x_0).$$

This transient chain allows to recover the recurrent one by the above procedure.

**Exercise 6.** Consider a transient process which is killed with probability $p$ at each passage in $\Delta$. Determine the associated energy and Green operator.

1.5 Transfer matrix

Let us suppose in this section that we are in the recurrent case: We can define a scalar product on the space $\mathbb{A}$ of functions on $E^o$ (oriented edges) as follows

$$\langle \omega, \eta \rangle_{\mathbb{A}} = \frac{1}{2} \sum_{x,y} C_{x,y} \omega^{x,y} \eta^{x,y}.$$  

Denoting as in [31] $df^{u,v} = f^v - f^u$, we note that $\langle df, dg \rangle_{\mathbb{A}} = e(f, g)$. In particular

$$\langle df, dG(\delta_y - \delta_x) \rangle_{\mathbb{A}} = df^{x,y}$$

Denote $\mathbb{A}_-$, $\mathbb{A}_+$ (the space of real valued functions on $E^o$ odd (even) for orientation reversal. Note that the spaces $\mathbb{A}_+$ and $\mathbb{A}_-$ are orthogonal for the scalar product defined on $\mathbb{A}$. The space $\mathbb{A}_-$ should be viewed as the space of "discrete differential forms".

Following this analogy, define for any $\alpha$ in $\mathbb{A}_-$, define $d^*\alpha$ by $(d^*\alpha)^x = -\sum_{y \in X} P_{y}^{x} \alpha^{x,y}$. Note it belongs to $\lambda^\perp$ as $\sum_{x,y} C_{x,y} \alpha^{x,y}$ vanishes.
We have
\[
\langle \alpha, df \rangle_{\mathbb{A}} = \frac{1}{2} \sum_{x,y} \lambda_x P_y^x \alpha^{y,x} (f^y - f^x)
\]
\[
= \frac{1}{2} \sum_{x \in X} (d^* \alpha)^x f^x \lambda_x - \frac{1}{2} \sum_{x,y} \lambda_x P_y^x \alpha^{y,x} f^y = \sum_{x \in X} (d^* \alpha)^x f^x \lambda_x
\]
as the two terms of the difference are in fact opposite since \(\alpha\) is skew-symmetric. The image of \(d\) and the kernel of \(d^*\) are therefore orthogonal in \(\mathbb{A}_{-}\).

We say \(\alpha\) in \(\mathbb{A}_{-}\) is harmonic iff \(d^* \alpha = 0\).

Moreover,
\[
e(f, f) = \langle df, df \rangle_{\mathbb{A}} = \sum_{x \in X} (d^* df)^x f^x \lambda_x.
\]

Note also that for any function \(f\),
\[
d^* df = -P f + f = -L f.
\]

\(d\) is the discrete analogue of the differential and \(d^*\) the analogue of its adjoint, depending on the metric which is here defined by the conductances. \(L\) is a discrete version of the Laplacian.

**Proposition 3.** The projection of any \(\alpha\) in \(\mathbb{A}_{-}\) on the image of \(d\) is \(dV d^* (\alpha)\).

**Proof.** Indeed, for any function \(g\),
\[
\langle \alpha, dg \rangle_{\mathbb{A}} = \langle d^* \alpha, g \rangle_{\mathbb{A}} = e(V d^* (\alpha), dg) = \langle dV d^* (\alpha), dg \rangle_{\mathbb{A}}.
\]

We now can come to the definition of the transfer matrix: Set \(\alpha_{(u,v)}^{x,y} = \pm C_{u,v}^{x,y}\) if \((x, y) = \pm (u, v)\) and 0 elsewhere. Then \(\lambda_x d^* \alpha_{(u,v)}(x) = \delta_v^x - \delta_u^x\) and \(dV d^* (\alpha_{(u,v)}) = dG(\delta_v - \delta_u)\). Note that given any orientation of the graph, the family \(\{\alpha_{(u,v)}^* = \sqrt{C_{u,v}^{x,y} C_{u,v}} (u, v) \in E^+\}\) is an orthonormal basis of \(\mathbb{A}_{-}\) (here \(E^+\) denotes the set of positively oriented edges).

The symmetric transfer matrix \(K^{(x,y),(u,v)}\), indexed by pairs of oriented edges, is defined to be
\[
K^{(x,y),(u,v)} = [dG(\delta_v - \delta_u)]^{x,y} = G(\delta_v - \delta_u)^y - G(\delta_v - \delta_u)^x
\]
\[
= <dG(\delta_y - \delta_x), dG(\delta_v - \delta_u) >_{\mathbb{A}}
\]
for \(x, y, u, v \in X\), with \(C_{x,y} C_{u,v} > 0\).

As \(dG((d^* \alpha)\lambda) = dV d^* (\alpha)\) is the projection \(\Pi(\alpha)\) of \(\alpha\) on the image of \(d\) in \(\mathbb{A}_{-}\), we have also:
\[
< \alpha_{(u,v)}, \Pi(\alpha_{(u',v')}) >_{\mathbb{A}} = < \alpha_{(u,v)}, dG(\delta_{u'} - \delta_{u'}) >_{\mathbb{A}} = K^{(u,v),(u',v')}
\]
For every oriented edge \( h = (x, y) \) in \( X \), set \( K^h = dG(\delta^y - \delta^x) \). We have \( \langle K^h, K^g \rangle_h = K^{h, g} \). We can view \( dG \) as a linear operator mapping the space measures of total charge zero into \( \mathbb{A}_- \). As measures of the form \( \delta_y - \delta_x \) span the space of measures of total charge zero, it is determined by the transfer matrix.

Note that \( d^* dG \upsilon = \upsilon / \lambda \) for any \( \upsilon \) of total charge zero and that for all \( \alpha \) in \( \mathbb{A}_- \), \( (d^* \alpha)\lambda \) has total charge zero.

Consider now, in the transient case, the transfer matrix associated with \( G^\Delta \).

We see that for \( x \) and \( y \) in \( X \),

\[
G^\Delta(\delta_x - \delta_y)^u - G^\Delta(\delta_x - \delta_y)^v = G(\delta_x - \delta_y)^u - G(\delta_x - \delta_y)^v.
\]

We can see also that \( G^\Delta(\delta_x - \delta_\Delta) = G\delta_x - \frac{\langle \lambda, G\delta_x \rangle}{\lambda(X^\Delta)} \). So the same identity holds in \( X^\Delta \).

Therefore, as \( G^{x, \Delta} = 0 \), in all cases,

\[
K^{(x, y), (u, v)} = G^{x, u} + G^{y, v} - G^{x, v} - G^{y, u}
\]

**Exercise 7.** Cohomology and complex transition matrices.

Consider, in the recurrent case, \( \omega \in \mathbb{A}_- \) such that \( d^* \omega = 0 \). Note that the space \( H^1 \) of such \( \omega \)'s is isomorphic to the first cohomology space, defined as the quotient \( \mathbb{A}_- / \text{Im}(d) \). Prove that \( P(I + i\omega) \) is \( \lambda \)-adjoint on \( X \), maps 1 onto 1 and that we have \( E_x(\prod_{j=0}^{n-1}(1 + \omega(\xi_j, \xi_{j+1}))1_{\{\xi_n=y\}}) = [(P(I + i\omega)]^n_y \).
Chapter 2
Loop measures

2.1 A measure on based loops

We denote by $\mathbb{P}^x$ the family of probability laws on piecewise constant paths defined by $P_t$.

$$\mathbb{P}^x(\gamma(t_1) = x_1, ..., \gamma(t_h) = x_h) = P_{t_1}(x, x_1) P_{t_2-t_1}(x_1, x_2) ... P_{t_h-t_{h-1}}(x_{h-1}, x_h)$$

The corresponding process is a Markov chain in continuous time. It can also be constructed as the process $\xi_{N_t}$, where $\xi_n$ is the discrete time Markov chain starting at $x$, with transition matrix $P$, and $N_t$ an independent Poisson process.

In the transient case, the lifetime is a.s. finite and denoting by $p(\gamma)$ the number of jumps and $T_i$ the jump times, we have:

$$\mathbb{P}^x(p(\gamma) = k, \gamma_{T_i} = x_1, ..., \gamma_{T_k} = x_k, T_1 \in dt_1, ..., T_k \in dt_k) = \frac{C_{x,x_1}...C_{x_{k-1}x_k} \kappa_{x_k}}{\lambda_2 \lambda_{x_1}...\lambda_{x_k}} \mathbb{1}_{\{0 < t_1 < ... < t_k\}} e^{-t_k dt_1...dt_k}$$

For any integer $p \geq 2$, let us define a based loop with $p$ points in $X$ as a couple $l = (\xi, \tau) = ((\xi_m, 1 \leq m \leq p), (\tau_m, 1 \leq m \leq p+1))$ in $X^p \times \mathbb{R}_+^{p+1}$, and set $\xi_{p+1} = \xi_1$ (equivalently, we can parametrize the associated discrete based loop by $\mathbb{Z}/p\mathbb{Z}$). The integer $p$ represents the number of points in the discrete based loop $\xi = (\xi_1, ..., \xi_{p(\xi)})$ and will be denoted $p(\xi)$, and the $\tau_m$ are holding times. Note however that two time parameters are attached to the base point since the based loops do not in general end or start with a jump.

Based loops with one point ($p = 1$) are simply given by a pair $(\xi, \tau)$ in $X \times \mathbb{R}_+$.

Based loops have a natural time parametrization $l(t)$ and a time period $T(\xi) = \sum_{i=1}^{p(\xi)+1} \tau_i$. If we denote $\sum_{i=1}^{m} \tau_i$ by $T_m$: $l(t) = \xi_m$ on $[T_{m-1}, T_m)$ (with by convention $T_0 = 0$ and $\xi_1 = \xi_{p+1}$).
Let $\mathbb{P}_{t}^{x,y}$ denote the (non normalized) "bridge measure" on piecewise constant paths from $x$ to $y$ of duration $t$ constructed as follows:

If $t_1 < t_2 < \ldots < t_h < t$,

$$\mathbb{P}_{t}^{x,y}(l(t_1) = x_1, \ldots, l(t_h) = x_h) = [P_{t_1}]_{x_1}^{x_h}[P_{t_2-t_1}]_{x_1}^{x_1} \ldots [P_{t_h-t_{h-1}}]_{x_h}^{x_h} \frac{1}{\lambda_y}$$

Its mass is $p_{t}^{x,y} = [P_{t}]_{x}^{y}$. For any measurable set $A$ of piecewise constant paths indexed by $[0,t]$, we can also write

$$\mathbb{P}_{t}^{x,y}(A) = \mathbb{P}_{x}(A \cap \{x_t = y\}) \frac{1}{\lambda_y}$$

**Exercise 8.** Prove that $\mathbb{P}_{t}^{y,x}$ is the image of $\mathbb{P}_{t}^{x,y}$ by the operation of time reversal on paths indexed by $[0,t]$.

A $\sigma$-finite measure $\mu$ is defined on based loops by

$$\mu = \sum_{x \in X} \int_{0}^{\infty} \frac{1}{t} \mathbb{P}_{t}^{x,x} \lambda_x dt$$

**Remark 4.** The introduction of the factor $\frac{1}{t}$ will be justified in the following. See in particular formula 2.3. It can be interpreted as the normalization of the uniform measure on the loop, according to which the base point is chosen.

From the expression of the bridge measure, we see that by definition of $\mu$, if $t_1 < t_2 < \ldots < t_h < t$,

$$\mu(l(t_1) = x_1, \ldots, l(t_h) = x_h, T \in dt) = [P_{t_1+t-t_h}]_{x_1}^{x_h}[P_{t_2-t_1}]_{x_1}^{x_1} \ldots [P_{t_h-t_{h-1}}]_{x_h}^{x_h} \frac{1}{t} dt.$$ (2.1)

Note also that for $k > 1$, using the second expression of $\mathbb{P}_{t}^{x,y}$ and the fact that conditionally on $N_t = k$, the jump times are distributed like an increasingly reordered $k$–uniform sample of $[0,t]$

$$\lambda_x \mathbb{P}_{t}^{x,x}(p = k, \xi_1 = x_1, \xi_2 = x_2, \ldots, \xi_k = x_k, T_1 \in dt_1, \ldots, T_k \in dt_k)$$

$$= 1_{\{x=x_1\}} e^{-t} \frac{k!}{k!} P_{t_1}^{x_1} P_{t_2}^{x_2} \ldots P_{t_k}^{x_k} \lambda_x \{0 < t_1 < \ldots < t_k < t\} \frac{k!}{t^k} dt_1 \ldots dt_k$$

$$= 1_{\{x=x_1\}} [P_{t_1}^{x_1}]_{x_1}^{x_1} [P_{t_2}^{x_2} P_{t_3}^{x_2} \ldots P_{t_k}^{x_k}] \lambda_x \{0 < t_1 < \ldots < t_k < t\} e^{-t} dt_1 \ldots dt_k$$

Therefore,

$$\mu(p = k, \xi_1 = x_1, \ldots, \xi_k = x_k, T_1 \in dt_1, \ldots, T_k \in dt_k, T \in dt) = P_{t_1}^{x_1} \ldots P_{t_k}^{x_k} \lambda_x \{0 < t_1 < \ldots < t_k < t\} e^{-t} dt_1 \ldots dt_k$$ (2.2)

$$= P_{t}^{x} \lambda_x \{0 < t_1 < \ldots < t_k < t\} e^{-t} dt_1 \ldots dt_k$$ (2.3)
2.2 First properties

for \( k > 1 \).

Moreover, for one point-loops, \( \mu\{p(\xi) = 1, \xi_1 = x_1, \tau_1 \in dt\} = \frac{e^{-t}}{\zeta} dt \).

It is clear on these formulas that for any positive constant \( c \), the energy forms \( e \) and \( ce \) define the same loop measure.

2.2 First properties

Note that the loop measure is invariant under time reversal.

If \( D \) is a subset of \( X \), the restriction of \( \mu \) to loops contained in \( D \), denoted \( \mu^D \) is clearly the loop measure induced by the Markov chain killed at the exit of \( D \). This can be called the restriction property.

Let us recall that this killed Markov chain is defined by the restriction of \( \lambda \) to \( D \) and the restriction \( P^D \) of \( P \) to \( D^2 \) (or equivalently by the restriction \( e_D \) of the Dirichlet form \( e \) to functions vanishing outside \( D \)).

As \( \int \frac{k^{-1}}{k} e^{-t} dt = \frac{1}{k} \), it follows from (2.2) that for \( k > 1 \), on based loops,

\[
\mu(p(\xi) = k, \xi_1 = x_1, \ldots, \xi_k = x_k) = \frac{1}{k} P^{x_1}_{x_2} \cdots P^{x_k}_{x_1}.
\]

In particular, we obtain that, for \( k \geq 2 \)

\[
\mu(p = k) = \frac{1}{k} Tr(P^k)
\]

and therefore, as \( Tr(P) = 0 \), in the transient case:

\[
\mu(p > 1) = \sum_{2}^{\infty} \frac{1}{k} Tr(P^k) = -\log(\det(I - P)) = \log(\det(G) \prod_x \lambda_x)
\]

since (denoting \( M_\lambda \) the diagonal matrix with entries \( \lambda_x \)), we have

\[
\det(I - P) = \frac{\det(M_\lambda - C)}{\det(M_\lambda)}
\]

Note that \( \det(G) \) is defined as the determinant of the matrix \( G^{x,y} \). It is the determinant of the matrix representing the scalar product defined on \( \mathbb{R}^{|X|} \) (more precisely, on the space of measures on \( X \)) by \( G \) in any basis, orthonormal with respect to the natural euclidean scalar product on \( \mathbb{R}^{|X|} \).

Moreover

\[
\int p(l)1_{\{p > 1\}} \mu(dl) = \sum_{2}^{\infty} Tr(P^k) = Tr((I - P)^{-1} P) = Tr(GC)
\]
2.3 Loops and pointed loops

It is clear on formula (2.1) that $\mu$ is invariant under the time shift that acts naturally on based loops.

A loop is defined as an equivalence class of based loops for this shift. Therefore, $\mu$ induces a measure on loops also denoted by $\mu$.

A loop is defined by the discrete loop $\xi^\circ$ formed by the $\xi_i$ in circular order, (i.e. up to translation) and the associated holding times. We clearly have:

$$\mu(\xi^\circ = (x_1, x_2, ..., x_k)) = \prod_{i=1}^{k} x_{i+1}^{-P_x^{x_i}}$$

provided the loop is primitive i.e. does not have a non trivial period, as it is in this case formed by $p$ equivalent based loops. Otherwise, the right hand side should be divided by the multiplicity. However, loops are not easy to parametrize, that is why we will work mostly with based loops or with pointed loops. These are defined as based loops ending with a jump, or equivalently as loops with a starting point. They can be parametrized by a based discrete loop and by the holding times at each point. Calculations are easier if we work with based or pointed loops, even though we will deal only with functions independent of the base point.

The parameters of the pointed loop naturally associated with a based loop are $\xi_1, ..., \xi_p$ and

$$\tau_1 + \tau_{p+1} = \tau_i, \tau_i = \tau_i^*, 2 \leq i \leq p$$

An elementary change of variables, shows the expression of $\mu$ on pointed loops can be written:

$$\mu(p = k, \xi_i = x_i, \tau_i^* \in dt_i) = \prod_{i=1}^{k} x_{i+1}^{P_x^{x_i}} e^{-\sum_{i=1}^{k} t_i dt_1 ... dt_k}.$$  \hspace{1cm} (2.6)

Trivial ($p = 1$) pointed loops and trivial based loops coincide.

Note that loop functionals can be written

$$\Phi(\xi^\circ) = \sum_{p=k} 1_{p=k} \Phi_k((\xi_i, \tau_i^*), i = 1, ..., k)$$

with $\Phi_k$ invariant under circular permutation of the variables $(\xi_i, \tau_i^*)$.

Then, for non negative $\Phi_k$

$$\int \Phi_k(\xi^\circ) \mu(dl) = \sum_{p=k} \int \Phi_k((x_i, t_i)i = 1, ..., k) \prod_{i=1}^{k} x_{i+1}^{P_x^{x_i}} e^{-\sum_{i=1}^{k} t_i dt_1 ... dt_k}$$

and by invariance under circular permutation, the term $t_1$ can be replaced by any $t_i$. Therefore, adding up and dividing by $k$, we get that
\[ \int \Phi_k(l^*) \mu(dl) = \sum \frac{1}{k} \Phi_k((x_i, t_i) i = 1, \ldots, k) P_{x_2} \ldots P_{x_k} e^{-\sum t_i dt_1 \ldots dt_k}. \]

The expression on the right side, applied to any pointed loop functional defines a different measure on pointed loops, we will denote by \( \mu^* \). It induces the same measure as \( \mu \) on loops.

We see on this expression that conditionally on the discrete loop, the holding times of the loop are independent exponential variables.

\[ \mu^*(p = k, \xi_i = x_i, \tau_i^* \in dt_i) = \frac{1}{k} \prod_{i \in \mathbb{Z}/p\mathbb{Z}} \frac{C_{\xi_i, \xi_{i+1}}}{\lambda_{\xi_i}} e^{-t_i dt_i} \tag{2.7} \]

Conditionally on \( p(\xi) = k \), \( T \) is a gamma variable of density \( \frac{k^{k-1}}{(k-1)!} e^{-t} \) on \( \mathbb{R}_+ \) and \( (\frac{T}{k}, 1 \leq i \leq k) \) an independent ordered \( k \)-sample of the uniform distribution on \( (0, T) \) (whence the factor \( \frac{1}{k} \)). Both are independent, conditionally on the number of points \( p \) of the discrete loop. We see that \( \mu \) on based loops is obtained from \( \mu \) on the loops by choosing the base point uniformly.

On the other hand, it induces a choice of \( \xi_1 \) biased by the size of the \( \tau_i^* \)'s, different from \( \mu^* \) for which this choice is uniform (whence the factor \( \frac{1}{k} \)). But we will consider only loop functionals for which \( \mu \) and \( \mu^* \) coincide.

It will be convenient to rescale the holding time at each \( \xi_i \) by \( \lambda_{\xi_i} \) and set

\[ \tilde{\tau}_i = \frac{\tau_i^*}{\lambda_{\xi_i}}. \]

The discrete part of the loop is the most important, though we will see that to establish a connection with Gaussian fields it is necessary to consider occupation times. The simplest variables are the number of jumps from \( x \) to \( y \), defined for every oriented edge \( (x, y) \)

\[ N_{x,y} = \# \{ i : \xi_i = x, \xi_{i+1} = y \} \]

(recall the convention \( \xi_{p+1} = \xi_1 \)) and

\[ N_x = \sum_y N_{x,y} \]

Note that \( N_x = \# \{ i \geq 1 : \xi_i = x \} \) except for trivial one point loops for which it vanishes.

Then, the measure on pointed loops (2.6) can be rewritten as:
\[\mu^*(p = 1, \xi = x, \tau \in dt) = e^{-\lambda_x t} dt\] and

\[\mu^*(p = k, \xi_i = x_i, \tau_i \in dt_i) = \frac{1}{k} \prod_{x,y} C_{x,y} \prod_{x} \lambda_x^{-N_x} \prod_{i \in \mathbb{Z}/p} \lambda_{\xi_i} e^{-\lambda_{\xi_i} t_i} dt_i.\]  

Another bridge measure \(\mu^{x,y}\) can be defined on paths \(\gamma\) from \(x\) to \(y\):

\[\mu^{x,y}(d\gamma) = \int_0^\infty P_{x,y}^s(d\gamma) dt.\]

Note that the mass of \(\mu^{x,y}\) is \(G_{x,y}\). We also have, with similar notations as the one defined for loops, \(p\) denoting the number of jumps

\[\mu^{x,y}(p(\gamma) = k, \gamma_{T_1} = x_1, \ldots, \gamma_{T_{k-1}} = x_{k-1}, T_1 \in d\gamma_1, \ldots, T_k \in d\gamma_k, T \in dt) = \frac{C_{x,x_1} C_{x_1,x_2} \cdots C_{x_{k-1},y}}{\lambda_x^{N_{x_1}} \cdots \lambda_y} \tau_{0 < t_1 < \cdots < t_k < t} e^{-t_1 dt_1 \cdots dt_k dt}.\]

From now on, we will assume, unless otherwise specified, that we are in the transient case.

For any \(x \neq y\) in \(X\) and \(s \in [0, 1]\), setting \(P^{(s)}_v = P^v_s\) if \((u,v) \neq (x,y)\) and \(P^{(s)}_y = s P^y_s\), we can prove in the same way as (2.5) that:

\[\mu(s^{N_{x,y}} 1_{p > 1}) = -\log(\det(I - P^{(s)})).\]

Differentiating in \(s = 1\), and remembering that for any invertible matrix function \(M(s)\), \(\frac{d}{ds} \log(\det(M(s))) = Tr(M'(s)M(s)^{-1})\), it follows that:

\[\mu(N_{x,y}) = [(I - P)^{-1}] y^x = G^{x,y} C_{x,y}\]

and

\[\mu(N_x) = \sum_y \mu(N_{x,y}) = \lambda_x G^{x,x} - 1\]  

(2.10)

(as \(G(M_x - C) = Id\)).

**Exercise 9.** Show that more generally

\[\mu(N_{x,y})(N_{x,y} - 1) \cdots (N_{x,y} - k + 1) = (k - 1)!(G^{x,y} C_{x,y})^k.\]

Hint: Show that if \(M''(s)\) vanishes,

\[
\frac{d^n}{ds^n} \log(\det(M(s))) = (-1)^{n-1}(n-1)!Tr((M'(s)M(s)^{-1})^n).
\]

**Exercise 10.** Show that more generally, if \(x_i, y_i\) are \(n\) distinct oriented edges:

\[\mu(\prod N_{x_i, y_i}) = \prod C_{x_i, y_i} \frac{1}{n} \sum_{\sigma \in S_n} \prod G^{y_{\sigma(i)} x_{\sigma(i) + 1}}.\]
2.4 Occupation field

Hint: Introduce \( [P(s_1, \ldots, s_n)]_y \) equal to \( P_y \) if \((x, y) \neq (x_i, y_i)\) for all \(i\), and equal to \( s_i P_{y_i} \) if \((x, y) = (x_i, y_i)\).

We finally note that if \( C_{x,y} > 0 \), any path segment on the graph starting at \( x \) and ending at \( y \) can be naturally extended into a loop by adding a jump from \( y \) to \( x \). We have the following

**Proposition 4.** For \( C_{x,y} > 0 \), the natural extension of \( \mu^{x,y} \) to loops coincides with \( \frac{N_{y,x}(l)}{C_{x,y}} \mu(dl) \).

**Proof.** The first assertion follows from the formulas, noticing that a loop \( l \) can be associated to \( N_{y,x}(l) \) distinct bridges from \( x \) to \( y \), obtained by "cutting" one jump from \( y \) to \( x \).

Note that a) shows that the loop measure induces bridge measures \( \mu^{x,y} \) when \( C_{x,y} > 0 \). If \( C_{x,y} \) vanishes, an arbitrarily small positive perturbation creating a non vanishing conductance between \( x \) and \( y \) allows to do it. More precisely, denoting by \( e^{(\varepsilon)} \) the energy form equal to \( e \) except for the additional conductance \( C_{x,y}^{(\varepsilon)} = \varepsilon \), \( \mu^{x,y} \) can be represented as \( \frac{d}{d\varepsilon} \mu^{x,y} |_{\varepsilon=0} \).

2.4 Occupation field

To each loop \( l^o \) we associate local times, i.e. an occupation field \( \{\hat{\ell}_{x}, x \in X\} \) defined by

\[
\hat{\ell}^{x} = \int_{0}^{\tau_{l}} 1_{\{t(s)=x\}} \frac{1}{\lambda(s)} ds = \sum_{i=1}^{p(l)} 1_{\{\xi_{i}=x\}} \hat{\tau}_{i}
\]

for any representative \( l = (\xi_{i}, \tau^{*}_{i}) \) of \( l^o \).

For a path \( \gamma \), \( \hat{\gamma} \) is defined in the same way.

Note that

\[
\mu((1 - e^{-\alpha t})1_{\{p=1\}}) = \int_{0}^{\infty} e^{-t}(1 - e^{-\frac{\alpha t}{x}}) dt = \log(1 + \frac{\alpha}{\lambda x}). \quad (2.11)
\]

The proof goes by expanding \( 1 - e^{-\frac{\alpha t}{x}} \) before the integration, assuming first that \( \alpha \) is small and then by analyticity of both members, or more elegantly, noticing that \( \int_{a}^{b} (e^{-cx} - e^{-dx}) \frac{dx}{x} \) is symmetric in \((a, b)\) and \((c, d)\), by Fubini’s theorem.

In particular, \( \mu(\hat{\ell}^{x} 1_{\{p=1\}}) = \frac{1}{x} \).

From formula \((2.7)\), we get easily that the joint conditional distribution of \((\hat{\ell}^{x}, x \in X)\) given \((N_{x}, x \in X)\) is a product of gamma distributions. In particular, from the expression of the moments of a gamma distribution, we get that for any function \( \Phi \) of the discrete loop and \( k \geq 1 \),
\[
\mu((\hat{l}^x)^k 1_{\{p>1\}} \Phi) = \lambda_x^{-k} \mu((N_x + k - 1) (N_x + 1) N_x \Phi).
\]

In particular, by (2.10) \( \mu(\hat{l}^x) = \frac{1}{\lambda_x} [\mu(N_x) + 1] = G^{x,x}. \)

Note that functions of \( \hat{l} \) are not the only functions naturally defined on the loops. Other such variables of interest are, for \( n \geq 2 \), the multiple local times, defined as follows:

\[
\hat{l}^{x_1, \ldots, x_n} = \sum_{j=0}^{n-1} \int_{0 < t_1 < \ldots < t_n < T} 1_{\{l(t_1) = x_{1+j}, \ldots, l(t_{n-j}) = x_n, \ldots, l(t_n) = x_j\}} \prod_{i=1}^{n-1} \frac{1}{\lambda_{x_i}} dt_i.
\]

It is easy to check that, when the points \( x_i \) are distinct,

\[
\hat{l}^{x_1, \ldots, x_n} = \sum_{j=0}^{n-1} \sum_{1 \leq t_1 < \ldots < t_n \leq \mu(l)} \prod_{i=1}^{n} 1_{\{\xi_{i+1} = x_{i+1}\}} \hat{r}_{t_i}.
\]

(2.12)

Note that in general \( \hat{l}^{x_1, \ldots, x_k} \) cannot be expressed in terms of \( \hat{l} \), but

\[
\hat{l}^{x_1, \ldots, x_n} = \frac{1}{n} \sum_{\sigma \in S_n} \hat{l}^{x_{\sigma(1)}, \ldots, x_{\sigma(n)}}.
\]

In particular, \( \hat{l}^{x_1, \ldots, x_n} = \frac{1}{(n-1)!} (\hat{l}^x)^n \). It can be viewed as an \( n \)-th self intersection local time.

One can deduce from the definitions of \( \mu \) the following:

**Proposition 5.** \( \mu(\hat{l}^{x_1, \ldots, x_n}) = G^{x_1,x_2} G^{x_2,x_3} \cdots G^{x_n,x_1}. \)

In particular, \( \mu(\hat{l}^{x_1, \ldots, x_n}) = \frac{1}{n} \sum_{\sigma \in S_n} G^{x_{\sigma(1)}, x_{\sigma(2)}} G^{x_{\sigma(2), x_{\sigma(3)}}} \cdots G^{x_{\sigma(n), x_{\sigma(1)}}}. \)

**Proof.** Let us denote \( \frac{1}{\lambda_x} [P_t]_{xy} \) by \( p_t(x,y) \) or \( p_t(x,y) \). From the definition of \( \hat{l}^{x_1, \ldots, x_n} \) and \( \mu, \mu(\hat{l}^{x_1, \ldots, x_n}) \) equals:

\[
\sum_{x} \lambda_x \sum_{j=0}^{n-1} \int_{\{0 < t_1 < \ldots < t_n < t\}} 1_t p_{t_1}(x, x_{1+j}) \cdots p_{t_n}(x_{n+j}, x) \prod_{i=1}^{n} dt_i dt.
\]

where sums of indices \( k+j \) are computed mod\( (n) \). By the semigroup property, it equals

\[
\sum_{j=0}^{n-1} \int_{\{0 < t_1 < \ldots < t_n < t\}} 1_t p_{t_2-t_1}(x_{1+j}, x_{2+j}) \cdots p_{t_1+t-t_n}(x_{n+j}, x_{1+j}) \prod_{i=1}^{n} dt_i dt.
\]

Performing the change of variables \( v_2 = t_2 - t_1, \ldots, v_n = t_n - t_{n-1}, v_1 = t_1 + t - t_n \), and \( v = t_1 \), we obtain:
\[\begin{align*}
\sum_{j=0}^{n-1} \int_{\{0<v<v_1,0<v_n\}} \frac{1}{v_1 + \ldots + v_n} p_{v_2}(x_{1+j},x_{2+j}) \ldots p_{v_1}(x_{n+j},x_{1+j}) \prod dv_i dv
\end{align*}\]

\[= \sum_{j=0}^{n-1} \int_{\{0<v_1\}} \frac{v_1}{v_1 + \ldots + v_n} p_{v_2}(x_{1+j},x_{2+j}) \ldots p_{v_1}(x_{n+j},x_{1+j}) \prod dv_i \]

\[= \sum_{j=1}^{n} \int_{\{0<v_j\}} \frac{v_j}{v_1 + \ldots + v_n} p_{v_2}(x_1,x_2) \ldots p_{v_1}(x_n,x_1) \prod dv_i \]

\[= \int_{\{0<v_n\}} p_{v_2}(x_1,x_2) \ldots p_{v_1}(x_n,x_1) \prod dv_i \]

\[= G^{x_1,x_2} G^{y_2,y_3} \ldots G^{y_n,x_1}.\]

Note that another proof can be derived from formula (2.12).

**Exercise 11.** (Shuffle product) Given two positive integers \(n > k\), let \(P_{n,k}\) be the family of partitions of \(\{1, 2, \ldots, n\}\) into \(k\) consecutive non-empty intervals \(I_i = (i_1, i_1 + 1, \ldots, i_{i+1} - 1)\) with \(i_1 = 1 < i_2 < \ldots < i_k < i_{k+1} = n + 1\).

Show that

\[\hat{\Psi}_{x_1, \ldots, x_n y_1, \ldots, y_m} = \sum_{j=0}^{m-1} \sum_{k=1}^{l_{\inf(n,m)}} \sum_{l \in P_{n,k}} \sum_{J \in P_{m,k}} \hat{\Psi}_{x_1, y_1 + J_1, x_2, \ldots, y_j + J_k}\]

where for example the term \(y_{j+j_1}\) appearing in the upper index should be read as \(j + j_1, \ldots, j + j_2 - 1\).

Similarly, we can define \(N(x_1, y_1)\ldots(x_n, y_n)\) to be

\[\sum_{j=0}^{n-1} \sum_{1 \leq i_1 < \ldots < i_n \leq p(l)} \prod_{l=1}^{n} 1\{\xi_{i_l} = x_{i_l+j}, \xi_{i_l+1} = y_{i_l+j}\} .\]

If \((x_i, y_i) = (x, y)\) for all \(i\), it equals \(N_{x,y}(N_{x,y-1})\ldots(N_{x,y-n+1})\).

Notice that

\[\prod_{\sigma \in S_n} N(x_1, y_1) = \frac{1}{n} \sum_{\sigma \in S_n} N(x_{\sigma(1)}, y_{\sigma(1)}) \ldots (x_{\sigma(n)}, y) .\]

Then we have the following:

**Proposition 6.** \(\int N(x_1, y_1)\ldots(x_n, y_n)(l) \mu(dl) = \left( \prod C_{x_i, y_i} \right) G^{y_1,x_2} G^{y_2,x_3} \ldots G^{y_n,x_1}.\)

The proof is left as exercise.

**Exercise 12.** For \(x_1 = x_2 = \ldots = x_k\), we could define different self intersection local times

\[\hat{\tau}_x(k) = \sum_{1 \leq i_1 < \ldots < i_k \leq p(l)} \prod_{l=1}^{k} 1\{\xi_{i_l} = x\} \hat{\tau}_{i_l}\]

which vanish on \(N_x < k\). Note that
2 Loop measures

\[ \hat{l}x(2) = \frac{1}{2}(\hat{l}x)^2 - \sum_{i=1}^{\nu(l)} 1_{\{\xi_{i,x} = \hat{l}i\}}(\hat{l}i)^2. \]

1. For any function \( \Phi \) of the discrete loop, show that

\[ \mu(\hat{l}x,2\Phi) = \lambda_x^{-2}\mu\left(\frac{N_x(N_x-1)}{2}1_{\{N_x \geq 2\}}\Phi\right). \]

2. More generally prove in a similar way that

\[ \mu(\hat{l}x,\Phi(k)) = \lambda_x^{-k}\mu\left(\frac{N_x(N_x-1)\ldots(N_x-k+1)}{k!}1_{\{N_x \geq k\}}\Phi\right). \]

Let us come back to the occupation field to compute its Laplace transform. From the Feynman-Kac formula, it comes easily that, denoting \( M_\chi \) the diagonal matrix with coefficients \( \chi x \)

\[ \mathbb{P}_t(\exp(t(P - I - M_\chi)))_x - \exp(t(P - I))_x \]

Integrating in \( t \) after expanding, we get from the definition of \( \mu \) (first for \( \chi \) small enough):

\[ \int (e^{-\hat{l}x} - 1)d\mu(l) = \sum_{k=1}^{\infty} \int_{0}^{\infty} [Tr((P - M_\chi)_x^k) - Tr((P)_x^k)] \frac{t^{k-1}}{k!}e^{-t}dt \]

\[ = \sum_{k=1}^{\infty} \frac{1}{k}[Tr((P - M_\chi)_x^k) - Tr((P)_x^k)] \]

\[ = - Tr(\log(I - P + M_\chi)) + Tr(\log(I - P)). \]

Hence, as \( Tr(\log) = \log(det) \)

\[ \int (e^{-\hat{l}x} - 1)d\mu(l) = \log[det(-L(-L + M_\chi)_x)^{-1})] \]

\[ = \log \det(I + VM_\chi) = \log \det(I + GM_\chi) \]

which now holds for all non negative \( \chi \) as both members are analytic in \( \chi \).

Besides, by the "resolvent" equation (1.1):

\[ \det(I + GM_\chi)^{-1} = \det(I - G_\chi M_\chi) = \frac{\det(G_\chi)}{\det(G)}. \]  (2.13)

Note that \( \det(I + GM_\chi) = \det(I + M_\sqrt{\chi}GM_\sqrt{\chi}) \) and \( \det(I - G_\chi M_\chi) = \det(I - M_\sqrt{\chi}G_\chi M_\sqrt{\chi}), \) so we can deal with symmetric matrices. Finally we have

**Proposition 7.** \( \mu(e^{-\hat{l}x} - 1) = - \log(\det(I + M_\sqrt{\chi}GM_\sqrt{\chi})) = \log\left(\frac{\det(G_\chi)}{\det(G)}\right) \)

Note that in particular \( \mu(e^{-st\frac{x}{a}} - 1) = - \log(1 + tG^{s,a}). \) Consequently, the image measure of \( \mu \) by \( \hat{l}x \) is \( 1_{\{s > 0\}} \frac{1}{8} \exp(-\frac{s}{G^{s,a}})ds. \)

Considering the Laguerre-type polynomials \( D_k \) with generating function
\[ \sum_{k=1}^{\infty} t^k D_k(u) = e^{ut} - 1 \]

and setting \( \sigma_x = G^{x,x} \), we have:

**Proposition 8.** The variables \( \frac{1}{\sqrt{\sigma_x}} \sigma_x^k D_k(\frac{\hat{\gamma}}{\sigma_x}) \) are orthonormal in \( L^2(\mu) \) for \( k > 0 \), and more generally

\[ \mathbb{E}(\sigma_x^k D_k(\frac{\hat{\gamma}}{\sigma_x}) \sigma_y^l D_l(\frac{\hat{\gamma}}{\sigma_y})) = \frac{1}{k} \delta_{k,l} (G^{x,y})^{2k}. \]

**Proof.** By proposition 7,

\[
\int (1 - e^{-\frac{\hat{\gamma}}{\sigma_x} x t}) (1 - e^{-\frac{\hat{\gamma}}{\sigma_y} y s}) \mu(dl) = \log(1 - \frac{\sigma_x t}{1 + \sigma_x t}) + \log(1 - \frac{\sigma_y s}{1 + \sigma_y s}) - \log \det \left( \frac{1 - \frac{\sigma_x t}{1 + \sigma_x t}}{1 - \frac{\sigma_y s}{1 + \sigma_y s}} \right) = - \log(1 - st (G^{x,y})^2).
\]

The proposition follows by expanding both sides in powers of \( s \) and \( t \), and identifying the coefficients.

Note finally that if \( \chi \) has support in \( D \), by the restriction property

\[ \mu(\{ x \in \Lambda \cap \hat{D} \}) = - \log(\det(I + M \chi G^D \sqrt{\chi})) = \log \left( \frac{\det(G^D)}{\det(G_D^\chi)} \right). \]

Here the determinants are taken on matrices indexed by \( D \) and \( G^D_D \) denotes the Green function of the process killed on leaving \( D \).

For paths we have \( P^{x,y}(e^{-\langle \hat{\gamma}, \chi \rangle}) = \frac{1}{\lambda_y} \exp(t(L - M \chi))_{x,y} \). Hence

\[ \mu^{x,y}(e^{-\langle \hat{\gamma}, \chi \rangle}) = \frac{1}{\lambda_y} ((I - P + M \chi \chi)^{-1})_{x,y} = [G^\chi]^{x,y}. \]

In particular, note that from the resolvent equation (1.1), we get that

\[ G^{y,x} = [G_{x\delta_x}]^{y,x} + [G_{y\delta_y}]^{y,x} G^{x,x}. \]

Hence \( \frac{[G_{x\delta_x}]^{y,x}}{G^{y,x}} = \frac{1}{1 + \varepsilon G^{x,x}} \) and therefore, we obtain:

**Proposition 9.** Under the probability \( \tilde{\mu}^{x,y} \), \( \hat{\gamma}^x \) follows an exponential distribution of mean \( G^{x,x} \).

Also \( \mathbb{E}(e^{-\langle \hat{\gamma}, \chi \rangle}) = \sum_y [G^\chi]^{x,y} \kappa_y \) i.e. \( [G^\chi] \kappa^x \).

Finally, let us note that a direct calculation shows the following result, analogous to proposition 4 in which the case \( x = y \) was left aside.

**Proposition 10.** On loops passing through \( x \), \( \mu^{x,x}(dl) = \hat{\gamma}^x \mu(dl) \).
An alternative way to prove the proposition is to check it on multiple local times, using exercise 11. It can be shown that the algebra formed by linear combinations of multiple local times generates the loop $\sigma$-field. Indeed, the discrete loop can be recovered by taking the multiple local time it indexes and noting it is the unique one of maximal index length among non vanishing multiple local times indexed by multiplets in which consecutive points are distinct. Then it is easy to get the holding times as the product of any of their powers can be obtained from a multiple local time.

**Remark 5.** Propositions 4 and 10 can be generalized: For example, if $x_i$ are $n$ points, $\tilde{\mu}^{x_1,...,x_n}(dl)$ can be obtained as the the image by circular concatenation of the product of the bridge measures $\mu^{x_{i-1},x_i}(dl)$ and $\prod \tilde{\mu}^{l(x)}(dl)$ can be obtained as the sum of the images, by concatenation in all circular orders, of the product of the bridge measures $\mu^{\lambda(x_{i-1}),x_i}(dl)$. If $(x_i,y_i)$ are $n$ oriented edges, $\prod \tilde{\mu}^{l(x_i-y_i)}(dl)$ can be obtained as the sum of the images, by concatenation in all circular orders $\sigma$, of the product of the bridge measures $\mu^{\lambda(x_{i-1}),x_i}(dl)$. One can also evaluate expressions of the form $\prod \tilde{\mu}^{l(x_{i-1},x_i)}(dl)$ as a sum of images, by concatenation in all circular orders, of a product of bridge measures.

### 2.5 Wreath products

The following construction gives an interesting information about the number of distinct points visited by the loop, which is more difficult to evaluate than the occupation measure.

Associate to each point $x$ of $X$ an integer $n_x$. Let $Z$ be the product of all the groups $\mathbb{Z}/n_x\mathbb{Z}$. On the wreath product space $X \times Z$, define a set of conductances $\tilde{C}_{(x,z),(x',z')}$ by:

$$\tilde{C}_{(x,z),(x',z')} = \frac{1}{n_xn_{x'}} C_{x,x'} \prod_{y \neq x,x'} 1\{z_y = z'_y\}$$

and set $\tilde{\kappa}_{(x,z)} = \kappa_x$. This means in particular that in the associated Markov chain, the first coordinate is an autonomous Markov chain on $X$ and that in a jump, the $Z$-configuration can be modified only at the point from which or to which the first coordinate jumps.

Denote by $\tilde{e}$ the corresponding energy form. Note that $\tilde{\lambda}_{(x,z)} = \lambda_x$.

Then, denoting $\tilde{\mu}$ the loop measure and $\tilde{P}$ the transition matrix on $X \times Z$ defined by $\tilde{e}$, we have the following

**Proposition 11.**
\[
\prod_{x \in \mathbb{R}} n_x \int_{\{p > 1\}} \prod_{x, N_x(i) > 0} \frac{1}{n_x} \mu(dl) = \tilde{\mu}(p > 1) = -\log(\det(I - \tilde{P})).
\]

In particular, if \(n_x = n\) for all \(x\),
\[
n^{|X|} \int_{\{p > 1\}} n^{-\#\{x, N_x(i) > 0\}} \mu(dl) = \tilde{\mu}(p > 1) = -\log(\det(I - \tilde{P})).
\]

**Proof.** Each time the Markov chain on \(X \times Z\) defined by \(\tilde{\sigma}\) jumps from a point above \(x\) to a point above \(y\), \(z_x\) and \(z_y\) are resampled according to the uniform distribution on \(Z/n_x Z \times Z/n_y Z\), while the other indices \(z_w\) are unchanged. It follows that
\[
[\tilde{P}^k]_{(x,z)} = \sum_{x_1, \ldots, x_{k-1}} P_{x_1}^{x} P_{x_2}^{x_1} \ldots P_{x_k}^{x_{k-1}} \prod_{y \in \{x, x_1, \ldots, x_{k-1}\}} \frac{1}{n_y}.
\]

Note that in the set \(\{x, x_1, \ldots, x_{k-1}\}\), distinct points are counted only once, even if the path visit them several times. There are \(\prod_{x \in X} n_x\) possible values for \(z\). The detail of the proof is left as an exercise.

In the case where \(X\) is a group and \(P\) defines a random walk, \(\tilde{P}\) is associated with a random walk on \(X \times Z\) equipped with its wreath product structure (Cf [40]).

## 2.6 Countable spaces

The assumption of finiteness of \(X\) can of course be relaxed but we will not do it in detail in these notes, though some infinite examples will be considered. On countable spaces, the previous results can be extended under transience conditions. In this case, the Dirichlet space \(\mathbb{H}\) is the space of all functions \(f\) with finite energy \(e(f)\) which are limits in energy norm of functions with finite support, and the energy defines a Hilbertian scalar product on \(\mathbb{H}\).

The energy of a measure is defined as \(\sup_{f \in \mathbb{H}} \frac{e(f)^2}{\mu(f)}\). Finitely supported measures have finite energy. Measures of finite energy are elements of the dual \(\mathbb{H}^*\) of the Dirichlet space. The potential \(G\mu\) is well defined for all finite energy measures \(\mu\), by the identity \(e(f, G\mu) = \langle f, \mu \rangle\), valid for all \(f\) in the Dirichlet space. The energy of the measure \(\mu\) equals \(e(G\mu) = \langle G\mu, \mu \rangle\) (see [12] for more information).

It should also be noted that the submarkovianity of \(P\) (i.e. the non negativity of \(\kappa\)) is not essential in the construction of the loop measure \(\mu\). It has only to be positive and \(I - P\) has to be invertible.

Most important examples of countable graphs are the non ramified covering of finite graphs (Recall that non ramified means that the projection
is locally one to one, i.e. that the projection on \( X \) of each vertex \( v \) of the covering space has the same number of incident edges as \( v \). Consider a non ramified covering graph \((Y, F)\) defined by a normal subgroup \( H_{x_0} \) of \( \Gamma_{x_0} \). The conductances \( C \) and the measure \( \lambda \) can be lifted in an obvious way to \( Y \) as \( H_{x_0} \backslash \Gamma_{x_0} \)-periodic functions but the associated Green function \( \hat{G} \) or semigroup are non trivial. By applying \( M_\lambda - C \), it is easy to check the following:

**Proposition 12.** \( G^{x,y} = \sum_{\gamma \in H_{x_0} \backslash \Gamma_{x_0}} \hat{G}^{i(x),\gamma(i(y))} \) for any section \( i \) of the canonical projection from \( Y \) onto \( X \).

Let us consider the universal covering (then \( H_{x_0} \) is trivial). It is easy to check it will be transient even in the recurrent case as soon as \((X, E)\) is not circular.

The expression of the Green function \( \hat{G} \) on a universal covering can be given exactly when it is a regular tree, i.e. in the regular graph case. In fact a more general result can be proved as follows:

Given a graph \((X, E)\), set \( d_x = \sum_y 1_{\{x, y\} \in E} \) (degree or valency of the vertex \( x \)), \( D_{x,y} = d_x \delta_{x,y} \) and denote \( A_{x,y} \) the incidence matrix \( 1_E(\{x, y\}) \).

Consider the Green function associated with \( \lambda_x = (d_x - 1)u + \frac{1}{u} \), with \( 0 < u < \inf(\frac{1}{d_x-1}, x \in X) \) and for \( \{x, y\} \in E, C_{x,y} = 1 \).

**Proposition 13.** On the universal covering \( \mathbb{T}_{x_0} \), \( \hat{G}^{x,y} = u^{d(x,y)} \frac{u}{1-u} \).

**Proof.** Note first that as \( \frac{1}{u} > d_x - 1 \), \( \kappa_x \) is positive for all \( x \). Then \( \hat{G} = (M_\lambda - C)^{-1} \) can be written \( \hat{G} = [u^{-1}I + (D - I)u - A]^{-1} \). Moreover, since we are on a tree,

\[
\sum_x A_{z,x} u^{d(x,y)} = (d_x - 1)u^{d(z,y)+1} + u^{d(z,y)-1}
\]

for \( z \neq y \), hence \( \sum_x (\lambda_x \delta_x^2 - A_{z,x}) u^{d(x,y)} = 0 \) for \( z \neq y \) and one checks it equals \( \frac{1}{u} - u \) for \( z = y \).

It follows from proposition 12 that for any section \( i \) of the canonical projection from \( \mathbb{T}_{x_0} \) onto \( X \),

\[
\sum_{\gamma \in \Gamma_{x_0}} u^{d(i(x),\gamma(i(y)))} = \left( \frac{1}{u} - u \right) G^{x,y}.
\]

### 2.7 Zeta functions for discrete loops

We present briefly the terminology of symbolic dynamics (see for example [38]) in this simple framework: Setting \( f(x_0, x_1, ..., x_n, ...) = \log(P_{x_0, x_1}) \), \( P \) induces the Ruelle operator \( L_f \) associated with \( f \).
2.7 Zeta functions for discrete loops

The pressure is defined as the logarithm of the highest eigenvalue $\beta$ of $P$. It is associated with a unique positive eigenfunction $h$ (normalized in $L^2(\lambda)$), by Perron Frobenius theorem. Note that $Ph = \beta h$ implies $\lambda hP = \beta \lambda h$ by duality and that in the recurrent case, the pressure vanishes and $h = \frac{1}{\sqrt{\lambda(X)}}$.

In continuous time, the lowest eigenvalue of $-L$ i.e. $1 - \beta$ plays the role of the pressure.

The equilibrium measure associated with $f$, $m = h^2 \lambda$ is the law of the stationary Markov chain defined by the transition probability $\frac{1}{\beta h}P^PH_y$.

If $\text{P}1 = 1$, i.e. $\kappa = 0$, we can consider a Feynman Kac type perturbation $P^{(\varepsilon \kappa)} = P M_{\varepsilon \kappa}$, with $\varepsilon \downarrow 0$ and $\kappa$ a positive measure. Perturbation theory (Cf for example [15]) shows that $\beta^{(\varepsilon \kappa)} - 1 = \frac{1}{\lambda(X)} \sum_x \frac{\lambda P^\varepsilon}{1 + \varepsilon \kappa} - 1 + o(\varepsilon) = -\varepsilon \kappa h \lambda + o(\varepsilon)$ and that $h^{(\varepsilon \kappa)} = \frac{1}{\sqrt{\lambda(X)}} + o(\varepsilon)$.

We deduce from that the asymptotic behaviour of

$$\int (e^{-\varepsilon \langle \ell, x \rangle} - 1) d\mu^{(\varepsilon \kappa)}(I) = \log(\det(I - P^{(\varepsilon \kappa)})) - \log(\det(I - P^{(\varepsilon (\kappa + \chi))}))$$

which is equivalent to $-\log(1 - \beta^{(\varepsilon (\kappa + \chi))}) + \log(1 - \beta^{(\varepsilon \kappa)})$ and therefore to

$$\log(\frac{\kappa(X)}{\kappa(X) + \chi(X)})$$

The study of relations between the loop measure $\mu$ and the zeta function $(\det(I - sP))^{-1}$ and more generally $(\det(I - P f P))^{-1}$ with $f$ a function on $[0, 1]$ can be done in the context of discrete loops.

$$\exp \left( \sum_{\text{based discrete loops}} \frac{1}{p(\xi)} s^{p(\xi)} \mu(\xi) \right) = (\det(I - sP))^{-1}$$

can be viewed as a type of zeta function defined for $s \in [0 \ 1/\beta)$

Primitive non trivial (based) discrete loops are defined as discrete based loops which cannot be obtained by the concatenation of $n \geq 2$ identical based loops. Loops are primitive iff they are classes of primitive based loops.

The zeta function has an Euler product expansion: if we denote by $\xi^\circ$ this discrete loop defined by the based discrete loop $\xi$, and set, for $\xi = (\xi_1, ..., \xi_k)$,

$$\mu(\xi^\circ) = P^\xi_{\xi_2} P^\xi_{\xi_2} ... P^\xi_{\xi_1},$$

it can be seen, by taking the logarithm, that:

$$(\det(I - sP))^{-1} = \exp \left( \sum_{\text{based discrete loops}} \frac{1}{p(\xi)} s^{p(\xi)} \mu(\xi) \right) = \prod_{\text{primitive discrete loops}} \left( 1 - \int s^{p(\xi^\circ)} \mu(\xi^\circ) \right)^{-1}$$
Chapter 3  
**Geodesic loops**

### 3.1 Reduction

Given any finite path $\omega$ with starting point $x_0$, the reduced path $\omega^R$ is defined as the geodesic arc defined by the endpoint of the lift of $\omega$ to $\mathcal{T}_{x_0}$.

Tree-contour-like based loops can be defined as discrete based loops whose lift to the universal covering are still based loops. Each link is followed the same number of times in opposite directions (backtracking). The reduced path $\omega^R$ can equivalently be obtained by removing all tree-contour-like based loops imbedded into it. In particular each loop $l$ based at $x_0$ defines an element $l^R$ in $\Gamma_{x_0}$.

![Based loop](image.png)

**Fig. 3.1** Based loop

This procedure is an example of *loop erasure*. In any graph, given a path $\omega$, the loop erased path $\omega^{LE}$ is defined by removing progressively all based loops imbedded in the path, starting from the origin. It produces a self avoiding path (and we see geodesics in $\mathcal{T}_{x_0}$ are self avoiding paths). Hence any non
ramified covering defines a specific reduction operation by composition of lift, loop erasure, and projection.

![Fig. 3.2 Loop erasure](image)

### 3.2 Geodesic loops and conjugacy classes

Then, we can consider loops i.e. equivalence classes of based loops under the natural shift.

Geodesic loops are of particular interest. Note their based loops representatives have to be "tailless": If γ is a geodesic based loop, with |γ| = n, the tail of γ is defined as γ₁γ₂...γᵢ₋₁γᵢ if i = sup(j; γ₁γ₂...γᵢ = γᵢ₊₁γᵢ₊₂...γᵢ₋ᵢ+₂) with \( \gamma_{n+1} = \gamma_1 \). The associated geodesic loop is obtained by removing the tail.

The geodesic loops are clearly in bijection with the set of conjugacy classes of the fundamental group. Indeed, if we fix a reference point \( x_0 \), a geodesic loop defines the conjugation class formed of the elements of \( \Gamma_{x_0} \) obtained by choosing a base point on the loop and a geodesic segment linking it to \( x_0 \). Any non trivial element of \( \Gamma_{x_0} \) can be obtained in this way.

Given a loop, there is a canonical geodesic loop associated with it. It is obtained by removing all tails imbedded in it. It can be done by removing one by one all tail edges (i.e. pairs of consecutive inverse oriented edges of the loop). Note that after removal of a tail edge, another tail edge cannot disappear, and that new tail edges appear during this process.

A closed geodesic based at \( x_0 \) is called primitive if it cannot be obtained as the concatenation of several identical closed geodesic, i.e. if it is not a non trivial power in \( \Gamma_{x_0} \). This property is clearly stable under conjugation. Let \( \mathcal{P} \) be corresponding set of primitive geodesic loops. They represent conjugacy classes of primitive elements of \( \Gamma \) (see [52]).
3.3 Geodesics and boundary

Geodesics lines (half-lines) on a graph are defined as paths without backtracking indexed by $\mathbb{Z}$ ($\mathbb{N}$).

Paths and in particular geodesics can be defined on $(X, E)$ or on a universal cover $\tilde{\mathcal{X}}$ and lifted or projected on any intermediate covering space. Two geodesic half lines are said to be confluent if their intersection is a half line.

Let us now take the point of view described in remark 1. Equivalence classes of geodesics half lines of $\tilde{\mathcal{X}}$ for the confluence relation define the boundary $\partial \mathcal{X}$ of $\mathcal{X}$. A geodesic half-line on $\mathcal{X}$ can therefore be defined by two points: its origin $Or$ and the boundary point $\theta$ towards which it converges. It projects on a geodesic half-line on $(X, E) = \Gamma \setminus \mathcal{X}$. The set of geodesic half lines on $(X, E)$ is identified with $\Gamma \setminus (\mathcal{X} \times \partial \mathcal{X})$ which projects canonically onto $X$.

There is a natural $\sigma$-field on the boundary generated by cylinder sets $B_g$ defined by half geodesics starting with a given oriented edge $g$.

Given any point $x_0$ in $\tilde{\mathcal{X}}$, assuming in this subsection that $\kappa = 0$, one can define a probability measure on the boundary called the harmonic measure and denoted $\nu_{x_0}$: $\nu_{x_0}(B_g)$ is the probability that the lift of the $P$-Markov chain starting at $x_0$ hits $g^+$ after its last visit to $g^-$.
Note that $\Gamma$ acts on the boundary in such a way that $\gamma^*(\nu_x) = \nu_{\gamma(x)}$, for all $\gamma \in \Gamma$ and $x \in \mathfrak{T}$. This harmonic measure induces a probability on the fiber above $\Gamma x$ in $\Gamma \setminus (\mathfrak{T} \times \partial \mathfrak{T})$, i.e. on half geodesics starting at the projection of $x$ on $X$.

Clearly, in the case of a regular graph, as the universal covering is a $r-$regular tree, $\nu_{x_0}(B_g) = \frac{1}{r} \frac{1}{(r-1)^{d(x_0,g)-1}}$, where $d$ denotes the distance in the tree. When conductances are all equal, $\nu_{x_0}(B_g)$ can also be computed but is in general distinct from the visibility measure from $x_0$, $\nu^{\text{vis}}_{x_0}(B_g)$, defined as $\frac{1}{a_{x_0}} \prod_{x_{i-1}}^{1} \frac{1}{d_{x_i-1}}, x_1, x_2, \ldots x_i, \ldots$ being the points of the geodesic segment linking $x_0$ to $g^-$. $\nu^{\text{vis}}_{x_0}$ is also a probability on $\partial \mathfrak{T}$.

There is an obvious canonical shift acting on half geodesics.

Note also that $\sum_{x \in \mathfrak{T}} \delta_x \nu^{\text{vis}}_x(d\theta)$ is a shift-invariant and $\Gamma$-invariant measure on the set of half-geodesics of $\mathfrak{T}$.

It can be shown it induces a canonical shift invariant and $\Gamma$-invariant probability on half geodesics on $X$ obtained by restricting the sum to any fundamental domain and normalizing by $|X|$. It is independent of the choice of the domain.

### 3.4 Closed geodesics and associated Zeta function

Recall that $\mathfrak{P}$ denotes the set of primitive geodesic loops.

Ihara’s zeta function $IZ(u)$ is defined for $0 \leq u < 1$ as

$$IZ(u) = \prod_{\gamma \in \mathfrak{P}} (1 - u^{p(\gamma)})^{-1}$$

It depends only on the graph.

Note that

$$u \frac{d}{du} IZ(u) = \sum_{\gamma \in \mathfrak{P}} \frac{p(\gamma) u^{p(\gamma)}}{1 - u^{p(\gamma)}} = \sum_{\gamma \in \mathfrak{P}} \sum_{n=1}^{\infty} p(\gamma) u^n p(\gamma) = \sum_{m=2}^{\infty} N_m u^m$$

where $N_m$ denotes the number of tailless geodesic based loops of length $m$.

Indeed, each primitive geodesic loop $\gamma$ traversed $n$ times still induces $p(\gamma)$ distinct tailless geodesic based loops. Therefore $IZ(u)$ can also be written as $\exp \left( \sum_{m=2}^{\infty} \frac{N_m u^m}{m} \right)$.

Similarly, one can define $\sum_{m=2}^{\infty} L_m u^m$ where $L_m$ denotes the number of geodesic based loops of length $m$. Recall that $A$ denotes the adjacency matrix of the graph, and $D$ the diagonal matrix whose entries are given by the degrees of the vertices.
Assume now that $0 < u < \inf\left(\frac{1}{d_x - 1}, x \in X\right)$. We will use again the Green function associated with $\lambda_x = (d_x - 1)u + \frac{1}{u}$ and, for $\{x, y\} \in E$, $C_{x,y} = 1$.

**Theorem 1.**

a) $\sum_{m=0}^{\infty} L_m u_m = (1 - u^2)Tr([I + (D - I)u^2 - uA]^{-1}) - |X|$.  

b) $IZ(u) = (1 - u^2)^{-\chi} \det(I - uA + u^2(D - I))^{-1}$ where $\chi$ denotes the Euler number $|E| - |X|$ of the graph.

Note that an expansion for small $u$ allows to compute the $L_m$’s. In particular, we can check that $L_2 = 0$.

**Proof.** We adapt the approach of Stark-Terras ([52]).

a) As geodesic loops based in $x_0$ are in bijection with $\Gamma_{x_0}$, it follows from proposition 12 that $|V| + \sum_{m=0}^{\infty} L_m u_m = \left(\frac{1}{u} - u\right)Tr(G) = (1 - u^2)Tr([I + (D - I)u^2 - uA]^{-1})$.

b) Given a geodesic loop $l$ and a base point $y$ of $l$, let $S_{x,y,l}$ be the sum of the coefficients $u^{p(\delta)}$, where $\delta$ varies on all geodesic loops based at $x$ composed with $l$ and a tail ending at $y$. If $x = y$, we have $S_{y,y,l} = u^{p(l)}$. Set $S_{x,l} = \sum_y S_{x,y,l}$.

Clearly, for any section $i$ of the canonical projection from $\Sigma_x$ onto $X$,

$\sum_{y,l} S_{x,y,l} = \sum_{\gamma \in \Gamma_{x} - \{I\}} u^{d(i(x), \gamma i(x))} = \left(\frac{1}{u} - u\right)G^{x,x} - 1$.

On the other hand, considering first the tailless case, then the case where the tail has length 1, and finally decomposing the case where the tail has length at least two according to the position of the point of the tail next to $x$, (denoted by $x'$), we obtain the expression:

$\sum_{x} S_{x,y,l} = u^{p(l)} + (d_y - 2) u^{p(l)+2} + \sum_{x' \neq y} (d_{x'} - 1) u^{2} S_{x',y,l} = u^{p(l)} - u^{p(l)+2} + \sum_{x} (d_x - 1) u^{2} S_{x,y,l}$

summing in $y$, it comes that

$\sum_{x} S_{x,l} = p(l)(u^{p(l)} - u^{p(l)+2}) + \sum_{x} (d_x - 1) u^{2} S_{x,l}.$

Then, summing on all geodesic loops $l$

$\sum_{x} \left(\frac{1}{u} - u\right)G^{x,x} - 1 = (1 - u^2)(\sum N_m u_m^m) + \sum_{x} (d_x - 1) u^{2} \left(\frac{1}{u} - u\right)G^{x,x} - 1.$

Therefore,
\[ \sum N_m u^m = Tr((I - u^2(D - I))(I + (D - I)u^2 - uA)^{-1} - (1 - u^2)^{-1}I) \\
= Tr(I - (2u^2(D - I) - uA)[I + (D - I)u^2 - uA]^{-1} \\
- (1 - u^2)^{-1}(I - u^2(D - I)) \\
= Tr((2u^2(D - I) - uA)[I + (D - I)u^2 - uA]^{-1} + (1 - u^2)^{-1}(u^2(D - 2I)). \]

To conclude note that
\[ \frac{d}{du} \log(\det(I + (D - I)u^2 - uA)) = Tr((2u(D - I) - A)[I + (D - I)u^2 - uA]^{-1}) \]
and that \( u^2 Tr(D - 2I) = 2u^2 \chi. \)

An alternative proof

Other proofs can be found in the literature, especially the following one due to Kotani-Sunada ([16]):

On the line graph, we define a transfer operator \( Q_{(x,y)}^{(y',z')} = \delta_{y'}^y 1(z \neq x). \)
Then, as \( \log(\det(I - uQ)^{-1}) = \sum \frac{u^n}{n} Tr(Q^n) \) and \( Tr(Q^n) = N_n \), we have
\[ IZ(u) = \det((I - uQ)^{-1}} \]

Define the linear map \( T \), from \( \mathbb{A} \) to functions on \( X \) by \( T \alpha(x) = \sum_{y, (x,y) \in E} \alpha(x, y). \)
Define a linear transformation \( \tau \) on \( \mathbb{A} \) by \( \tau \alpha(e) = \alpha(-e). \) Define \( S \) the linear map from functions on \( X \) to \( \mathbb{A} \) defined by \( Sf(x, y) = f(y). \) Note that \( TrS = D, TS = A, \) and \( Q = -\tau + ST. \)

Then, for any scalar \( u \), \( (I - u\tau)(I - uQ) = (1 - u^2)I - (I - u\tau)uST \) and
\[ (I - uQ)(I - u\tau) = (1 - u^2)I - uST(I - u\tau). \] (3.1)

Therefore \( T(I - u\tau)(I - uQ) = ((1 - u^2)T - uT(I - u\tau)ST) = (I + u^2(D - I) - uA)T \) and
\[ T(I - u\tau)(I - uQ)(I - u\tau) = (I + u^2(D - I) - uA)T(I - u\tau). \]

Moreover \( (I - uQ)(I - u\tau)S = S((1 - u^2)I - uT(I - u\tau)S) \) and
\[ (I - uQ)(I - u\tau)S = S(I + u^2(D - I) - uA). \] (3.2)

It follows from these two last identities that \( \text{Im}(S) \) and \( \text{Ker}(T(I - u\tau)) \) are stable under \( (I - uQ)(I - u\tau). \)

Note that \( S \) is the dual of \(-T\tau\): Indeed, for any function \( f \) on vertices and \( \alpha \) on oriented edges,
\sum_{(x,y) \in E} \alpha(x,y)Sf(x,y) = \sum_{(x,y) \in E} \alpha(x,y)f(y) = -\sum_y T\alpha(y)f(y).

Therefore, \( \dim(\text{Im}(S)) + \dim(\text{Ker}(T\tau)) = 2|E| \).

Note also that \( \dim(\text{Ker}(T\tau)) = \dim(\text{Ker}(T)) = \dim(\text{Ker}(T(I-u\tau))) \) (as \( u < 1 \)).

Moreover, except for a finite set of \( u \)'s, \( \text{Im}(S) \cap \text{Ker}(T(I-u\tau)) = \{0\} \).

Indeed \( T(I-u\tau)S = A - uD \) which is invertible, except for a finite set of \( u \)'s.

Note that (3.1) implies that \( (I-uQ)(I-u\tau) \) equals \( (1-u^2)I \) on \( \text{Ker}(T(I-u\tau)) \) and that (3.2) implies it equals \( S(I + u^2(D-I) - uA)S^{-1} \) on \( \text{Im}(S) \).

It comes that:

\[
\det((I-u\tau)(I-uQ)) = (1-u^2)^{2|E| - |X|} \det(I + u^2(D-I) - uA)
\]

On the other hand, \( \det((I-u\tau)) = (1-u^2)^{|E|} \), which allows to conclude.
Chapter 4
Poisson process of loops

4.1 Definition

Still following the idea of [20], which was already implicitly in germ in [54], define, for all positive \( \alpha \), the Poissonian ensemble of loops \( \mathcal{L}_\alpha \) with intensity \( \alpha \mu \).

Note also that these Poissonian ensembles can be considered for fixed \( \alpha \) or as a point process of loops indexed by the "time" \( \alpha \). In that case, \( \mathcal{L}_\alpha \) is an increasing set of loops with stationary increments. We will denote by \( \mathcal{LP} \) the associated Poisson point process of intensity \( \mu(dl) \otimes \text{Leb}(d\alpha) \) (\( \text{Leb} \) denoting Lebesgue measure on the positive half-line). It is formed by a countable set of pairs \( (l_i, \alpha_i) \) formed by a loop and a time. We denote by \( \mathbb{P} \) its distribution.

Recall that for any functional \( \Phi \) on the loop space, vanishing on loops of arbitrary small length,

\[
\mathbb{E}(e^{i \sum_{l \in \mathcal{L}_\alpha} \Phi(l)}) = \exp(\alpha \int (e^{i \Phi(l)} - 1) \mu(dl))
\]

and for any positive functional \( \Psi \) on the loops space,

\[
\mathbb{E}(e^{-\sum_{l \in \mathcal{L}_\alpha} \Psi(l)}) = \exp(\alpha \int (e^{-\Psi(l)} - 1) \mu(dl))
\]

It follows that if \( \Phi \) is \( \mu \)-integrable, \( \sum_{l \in \mathcal{L}_\alpha} \Phi(l) \) is integrable and

\[
\mathbb{E}(\sum_{l \in \mathcal{L}_\alpha} \Phi(l)) = \int \Phi(l) \alpha \mu(dl).
\]

And if in addition \( \Phi^2 \) is \( \mu \)-integrable, \( \sum_{l \in \mathcal{L}_\alpha} \Phi(l) \) is square-integrable and

\[
\mathbb{E}((\sum_{l \in \mathcal{L}_\alpha} \Phi(l))^2) = \int \Phi^2(l) \alpha \mu(dl) + (\int \Phi(l) \alpha \mu(dl))^2.
\]
Recall also "Campbell formula" (Cf formula 3-13 in [17]): For any system of non negative or \( \mu \)-integrable loop functionals \( F_i \),

\[
\mathbb{E}
\left(
\sum_{l_1 \neq l_2 \ldots \neq l_k \in \mathcal{L}_\alpha}
\prod_{i=1}^{k} F_i(l_i)
\right)
= \prod_{i=1}^{k} \alpha \mu(F_i)
\]

(4.2)

Note the same results hold for functionals of \( \mathcal{LP} \).

Of course, \( \mathcal{L}_\alpha \) includes trivial loops. The periods \( \tau_l \) of the trivial loops based at any point \( x \) form a Poisson process of intensity \( \alpha e^{-t}t \). It follows directly from this ([39] and references therein) that we have the following

**Proposition 14.** The sum of these periods \( \sum \tau_l \) and the set of "frequencies" \( \sum \tau_l \) (in decreasing order) are independent and follow respectively a \( \Gamma(\alpha) \) and a Poisson – Dirichlet\((0, \alpha)\) distribution.

Note that by the restriction property, \( \mathcal{L}_\alpha^D = \{ l \in \mathcal{L}_\alpha, l \subseteq D \} \) is a Poisson process of loops with intensity \( \mu^D \), and that \( \mathcal{L}_\alpha^D \) is independent of \( \mathcal{L}_\alpha \setminus \mathcal{L}_\alpha^D \).

We denote by \( \mathcal{D}\mathcal{L}_\alpha \) the set of non trivial discrete loops in \( \mathcal{L}_\alpha \). Then, \( \mathbb{P}(\#\mathcal{D}\mathcal{L}_\alpha = k) = e^{-\alpha \mu(p>1) \mu(p>1)k^{k!}} \) and conditionally to their number, the discrete loops are independently sampled according to \( \frac{1}{\mu(p>1) \mu(p>1)} \mathcal{L}_\alpha^D \). In particular, if \( l_1, l_2, \ldots, l_k \) are distinct discrete loops

\[
\mathbb{P}(\mathcal{D}\mathcal{L}_\alpha = \{ l_1, l_2, \ldots, l_k \}) = e^{-\alpha \mu(p>1) \mu(p>1)} \prod_{i=1}^{k} \mu(l_i)
\]

\[
= \alpha^{k} \prod_{i=1}^{k} \frac{\det(G)}{\prod_{x} \lambda_x} \prod_{x,y} C_{x,y}^{\sum_{i=1}^{k} N_{x,y}(l_i)} \prod_{x} \lambda_x^{-\sum_{i=1}^{k} N_x(l_i)}.
\]

The general result (when the \( l_i \)'s are not necessarily distinct) follows from the multinomial distribution.

We can associate to \( \mathcal{L}_\alpha \) a \( \sigma \)-finite measure (in fact as we will see, it is finite when \( X \) is finite, and more generally if \( G \) is trace class) called local time or occupation field

\[
\widehat{\mathcal{L}}_\alpha = \sum_{l \in \mathcal{L}_\alpha} \widehat{l}.
\]

Then, for any non-negative measure \( \chi \) on \( X \)

\[
\mathbb{E}(e^{-<\widehat{\mathcal{L}}_\alpha, \chi>}) = \exp \left( \alpha \int (e^{-<\widehat{l}, \chi>}) - 1) d\mu(l) \right).
\]

and therefore by proposition 7 we have

**Corollary 1.** \( \mathbb{E}(e^{-<\widehat{\mathcal{L}}_\alpha, \chi>}) = \det(I + \sqrt{\chi}GM\sqrt{\chi})^{\alpha} = \left( \frac{\det(G\chi)}{\det(G)} \right)^{\alpha}. \)

Many calculations follow from this result.
Note first that \( \mathbb{E}(e^{-t\tilde{L}_x^\alpha}) = (1 + tG^{x,x})^{-\alpha} \). Therefore \( \tilde{L}_x^\alpha \) follows a gamma distribution \( \Gamma(\alpha, G^{x,x}) \), with density \( 1_{u > 0} \frac{\alpha^{\alpha-1} u^{\alpha-1}}{\Gamma(\alpha)} e^{-uG^{x,x}} \). When we let \( \alpha \) vary as a time parameter, we get a family of gamma subordinators, which can be called a "multivariate gamma subordinator".

We check in particular that \( \mathbb{E}(\tilde{L}_x^\alpha) = \alpha G^{x,x} \) which follows directly from \( \mu(\tilde{l}_x^\alpha) = G^{x,x} \).

**Exercise 13.** If \( L_\alpha = \{l_i\} \), check that the set of "frequencies" \( \tilde{l}_x^\alpha \) follows a Poisson-Dirichlet distribution of parameters \((0, \alpha)\).

Hint: use the \( \mu \)-distribution of \( \tilde{l}_x^\alpha \).

Note also that for \( \alpha > 1 \),

\[
\mathbb{E}(1 - \exp(-\frac{\tilde{L}_x^\alpha}{G^{x,x}}))^{-1} = \zeta(\alpha).
\]

For two points, it follows easily from corollary 1 that:

\[
\mathbb{E}(e^{-t\tilde{L}_x^\alpha}e^{-s\tilde{L}_y^\alpha}) = ((1 + tG^{x,x})(1 + sG^{y,y}) - st(G^{x,y})^2)^{-\alpha}
\]

This allows to compute the joint density of \( \tilde{L}_x^\alpha \) and \( \tilde{L}_y^\alpha \) in terms of Bessel and Struve functions.

We can condition the loop configuration on the set of associated non trivial discrete loops by using the restricted \( \sigma \)-field \( \mathcal{D}L_\alpha \) which contains the variables \( N_{x,y} \). We see from (2.11) and (2.7) that:

\[
\mathbb{E}(e^{-\langle \tilde{L}_\alpha, \chi \rangle} | \mathcal{D}L_\alpha) = \prod_x (\frac{\lambda_x}{\lambda_x + \chi_x})^{N_x^{(\alpha)} + \alpha}
\]

The distribution of \( \{N_x^{(\alpha)}, x \in X\} \) follows easily, from corollary 1 in terms of generating functions:

\[
\mathbb{E}(\prod_x s_x^{N_x^{(\alpha)} + 1}) = \det(\delta_{x,y} + \sqrt{\frac{\lambda_x(1 - s_x)}{s_x} G_{x,y} + \frac{\lambda_y(1 - s_y)}{s_y} G_{x,y}^{x,y}})^{-\alpha} \quad (4.3)
\]

so that the vector of components \( N_x^{(\alpha)} \) follows a multivariate negative binomial distribution (see for example [57]).

It follows in particular that \( N_x^{(\alpha)} \) follows a negative binomial distribution of parameters \(-\alpha\) and \( \frac{1}{\lambda_x G^{x,x}} \). Note that for \( \alpha = 1 \), \( N_x^{(1)} + 1 \) follows a geometric distribution of parameter \( \frac{1}{\lambda_x G^{x,x}} \).

Note finally that in the recurrent case, with the setting and the notations of subsection 2.7, denoting \( L^{(\alpha)}_{\alpha x} \) the Poisson process of loops of intensity

1 A subordinator is an increasing Levy process. See for example reference [1].
Poisson process of loops

\[ \varepsilon \alpha \mu^{(\varepsilon \kappa)} \], we get that the associated occupation field converges in distribution towards a random constant following a Gamma distribution.

Let us recall one important property of Poisson processes, known as Palm formula.

**Proposition 15.** Given any bounded functional \( \Phi \) on loops configurations and any integrable loop functional \( F \), we have:

\[
E(\sum_{l \in \mathcal{L}_\alpha} F(l)\Phi(L)) = \int E(\Phi(L_\alpha \cup \{l\}))\alpha F(l) \mu(dl).
\]

**Proof.** This is proved by considering first for \( \Phi(L_\alpha) \) the functionals of the form \( \sum_{l_1 \neq l_2 \ldots \neq l_q \in \mathcal{L}_\alpha} \prod_j G_j(l_j) \) (with \( G_j \) bounded and \( \mu \)-integrable) which span an algebra separating distinct configurations and applying formula (4.2) . Then, the common value of both members is \( \alpha^q \sum_{l_1 \neq l_2 \ldots \neq l_q} \mu(G_j) \prod_{l \neq j} \mu(G_l) \).

**Exercise 14.** Give an alternative proof of this proposition using formula (4.1).

The above proposition applied to \( F(l) = \hat{I}^{x,y}N^{(\alpha)}_{x,y} \) and propositions 4 and 10 yield the following:

**Corollary 2.**

\[
E(\Phi(L_\alpha)\hat{\lambda}_\alpha^{x,y}) = \alpha \int E(\Phi(L_\alpha \cup \{\gamma\}))\hat{\lambda}_\alpha^{x,y}(d\gamma) = \alpha \int E(\Phi(L_\alpha \cup \{\gamma\}))\mu^{x,y}(d\gamma)
\]

and if \( x \neq y \)

\[
E(\Phi(L_\alpha)N^{(\alpha)}_{x,y}) = \alpha \int E(\Phi(L_\alpha \cup \{\gamma\}))N_{x,y}(\gamma)\mu(d\gamma) = \alpha C_{x,y} \int E(\Phi(L_\alpha \cup \{\gamma\}))\mu^{x,y}(d\gamma).
\]

**Remark 6.** Proposition 15 and corollary 2 can be easily generalized to functionals of the Poisson process \( \mathcal{L}_\alpha \).

**Exercise 15.** Generalize corollary 2 to \( \hat{\lambda}_\alpha^{x,y} \), for \( x \neq y \).

### 4.2 Moments and polynomials of the occupation field

It is easy to check (and well known from the properties of the gamma distributions) that the moments of \( \hat{\lambda}_\alpha^{x} \) are related to the factorial moments of \( N_x^{(\alpha)} \):

\[
E((\hat{\lambda}_\alpha^{x})^k | \mathcal{DL}_\alpha) = \frac{(N_x^{(\alpha)} + k - 1 + \alpha)(N_x^{(\alpha)} + k - 2 + \alpha)\ldots(N_x^{(\alpha)} + \alpha)}{\lambda_x^k}
\]
Exercise 16. Denoting $\mathcal{L}_\alpha^+$ the set of non trivial loops in $\mathcal{L}_\alpha$, define

$$\widehat{\mathcal{L}}_{\alpha}^{x,(k)} = \sum_{m=1}^{k} \sum_{k_1 + \ldots + k_m = k} \sum_{l_1 \neq l_2 \ldots \neq l_m \in \mathcal{L}_\alpha^+} \prod_{j=1}^{m} \widehat{I}_{j}^{x,(k_j)}.$$ 

Deduce from exercise 12 that $E(\widehat{\mathcal{L}}_{\alpha}^{x,(k)} | D\mathcal{L}_\alpha) = \frac{1}{N_x} 1_{(N_x \geq k)} (N_x^{(\alpha)} - k + 1) \ldots (N_x^{(\alpha)} - 1) N_x^{(\alpha)}$

It is well known that Laguerre polynomials $L_k^{(\alpha-1)}$ with generating function

$$\sum_{0}^{\infty} t_k L_k^{(\alpha-1)}(u) = \frac{e^{-tu}}{(1-t)^{\alpha}}$$

are orthogonal for the $\Gamma(\alpha)$ distribution. They have mean zero and variance $\frac{L_k^{(\alpha+1)}}{\Gamma(\alpha)}$. Hence if we set $\sigma_x = G^{x,x}$ and $P_k^{\alpha,\sigma}(x) = (-\sigma)^k L_k^{(\alpha-1)}(\frac{x}{\sigma})$, the random variables $P_k^{\alpha,\sigma}(\widehat{\mathcal{L}}_{\alpha}^{x})$ are orthogonal with mean 0 and variance $\sigma^{2k} \frac{L_k^{(\alpha+1)}}{\Gamma(\alpha)}$, for $k > 0$.

Note that $P_k^{\alpha,\sigma}(\widehat{\mathcal{L}}_{\alpha}^{x}) = \widehat{\mathcal{L}}_{\alpha}^{x} - \alpha \sigma_x = \widehat{\mathcal{L}}_{\alpha}^{x} - E(\widehat{\mathcal{L}}_{\alpha}^{x})$. It will be denoted $\widehat{\mathcal{L}}_{\alpha}^{-x}$.

Moreover, we have $\sum_{0}^{\infty} t_k P_k^{\alpha,\sigma}(u) = \sum (-\sigma t)^k L_k^{(\alpha-1)}(\frac{u}{\sigma}) = \frac{e^{-\sigma tu}}{(1+\sigma t)^{\alpha}}$

Note that by corollary 1,

$$E\left(\frac{\widehat{\mathcal{L}}_{\alpha}^{-x}}{(1+\sigma_x t)^{\alpha}} \frac{\widehat{\mathcal{L}}_{\alpha}^{y}}{(1+\sigma_y s)^{\alpha}}\right) = \frac{1}{(1+\sigma_x t)^{\alpha} (1+\sigma_y s)^{\alpha}} \left((1+\sigma_x t)(1+\sigma_y s) - t \frac{s}{1+\sigma_x t} (G^{x,y})^2 \right)^{-\alpha}$$ 

Therefore, we get, by developing in entire series in $(s, t)$ and identifying the coefficients:

$$E(P_k^{\alpha,\sigma_x}(\widehat{\mathcal{L}}_{\alpha}^{x}), P_l^{\alpha,\sigma_y}(\widehat{\mathcal{L}}_{\alpha}^{y})) = \delta_{k,l} (G^{x,y})^{2k} \alpha^{(\alpha + 1) \ldots (\alpha + k - 1)} \frac{1}{k!}$$

(4.4)

Let us stress the fact that $G^{x,x}$ and $G^{y,y}$ do not appear on the right hand side of this formula. This is quite important from the renormalisation point of view, as we will consider in the last section the two dimensional Brownian motion for which the Green function diverges on the diagonal.

More generally one can prove similar formulas for products of higher order.

It should also be noted that if we let $\alpha$ increase, $(1 + \sigma_x t)^{-\alpha}$ $\exp(\frac{\widehat{\mathcal{L}}_{\alpha}^{x}}{1+\sigma_x t})$ and $P_k^{\alpha,\sigma_x}(\widehat{\mathcal{L}}_{\alpha}^{x})$ are $\sigma(\mathcal{L}_\alpha)$-martingales with expectations respectively equal to 1 and 0.

Note that since $G \chi A_\chi$ is a contraction, from determinant expansions given in [56] and [57], we have
\[
\det(I + M \sqrt{\chi} GM \sqrt{\chi})^{-\alpha} = 1 + \sum_{k=1}^{\infty} \frac{(-1)^k}{k!} \sum \chi_{i_1} \ldots \chi_{i_k} \text{Per}_\alpha(G_{i_l,i_m}, 1 \leq l, m \leq k).
\]

The \(\alpha\)-permanent \(\text{Per}_\alpha\) is defined as \[\sum_{\sigma \in S_k} \alpha^{m(\sigma)} G_{i_{\sigma(1)}} \ldots G_{i_{\sigma(k)}},\] with \(m(\sigma)\) denoting the number of cycles in \(\sigma\). Then, from corollary 1, it follows that:

\[
E(\langle \widehat{L}_\alpha, \chi \rangle^k) = \sum \chi_{i_1} \ldots \chi_{i_k} \text{Per}_\alpha(G_{i_l,i_m}, 1 \leq l, m \leq k).
\]

Note that an explicit form for the multivariate negative binomial distribution, and therefore, a series expansion for the density of the multivariate gamma distribution, follows directly (see [57]) from this determinant expansion.

It is actually not difficult to give a direct proof of this result. Thus, the Poisson process of loops provides a natural probabilistic proof and interpretation of this combinatorial identity (see [57] for an historical view of the subject).

We can show in fact that:

**Proposition 16.** For any \((x_1, \ldots x_k)\) in \(X^k\), \(E(\langle \tilde{L}_\alpha^{-x_1} \ldots \tilde{L}_\alpha^{-x_k} \rangle) = \text{Per}_\alpha(G_{i_l,i_m}, 1 \leq l, m \leq k)\)

**Proof.** The cycles of the permutations in the expression of \(\text{Per}_\alpha\) are associated with point configurations on loops. We obtain the result by summing the contributions of all possible partitions of the points \(i_1 \ldots i_k\) into a finite set of distinct loops. We can then decompose again the expression according to ordering of points on each loop. We can conclude by using the formula \(\mu(\tilde{L}_1 \ldots \tilde{L}_m) = G_{x_1,x_2} G_{x_2,x_3} \ldots G_{x_m,x_1}\) and Campbell formula (4.2).

**Remark 7.** We can actually, in the special case \(i_1 = i_2 = \ldots = i_k = x\), check this formula in a different way. From the moments of the Gamma distribution, we have that \(E((\tilde{L}_\alpha)^n) = (G^{x,x})^n \alpha(\alpha+1)\ldots(\alpha+n-1)\) and the \(\alpha\)-permanent can be written \(\sum d(n,k) \alpha^k\) where the coefficients \(d(n,k)\) are the numbers of \(n\)-permutations with \(k\) cycles (Stirling numbers of the first kind). One checks that \(d(n+1,k) = nd(n,k) + d(n, k-1)\).

Let \(S_k^0\) be the set of permutations of \(k\) elements without fixed point. They correspond to configurations without isolated points.

Set \(\text{Per}_\alpha^0(G_{i_l,i_m}, 1 \leq l, m \leq k) = \sum_{\sigma \in S_k^0} \alpha^{m(\sigma)} G_{i_{\sigma(1)}} \ldots G_{i_{\sigma(k)}}\). Then an easy calculation shows that:

**Corollary 3.** \(E(\langle \tilde{L}_\alpha^{-i_1} \ldots \tilde{L}_\alpha^{-i_k} \rangle) = \text{Per}_\alpha^0(G_{i_l,i_m}, 1 \leq l, m \leq k)\)
Proof. Indeed, the expectation can be written
\[
\sum_{p \leq k} \sum_{I \subseteq \{1, \ldots, k\}, |I| = p} (-1)^{k-p} \prod_{i \in I} G^{i,i} \Per_{\alpha}(G^{i,a,ib}, a, b \in I)
\]
and
\[
\Per_{\alpha}(G^{i,a,ib}, a, b \in I) = \sum_{J \subseteq I} \prod_{j \in J} G^{j,j} \Per_{\alpha}^{0}(G^{i,a,ib}, a, b \in J).
\]

Then, expressing \(\mathbb{E}(\tilde{L}_{\alpha}^{-i} \ldots \tilde{L}_{\alpha}^{-e})\) in terms of \(\Per_{\alpha}^{0}\)'s, we see that if \(J \subseteq \{1, \ldots, k\}, |J| < k\), the coefficient of \(\Per_{\alpha}^{0}(G^{i,a,ib}, a, b \in J)\) is
\[
\sum_{I, I \supseteq J} (-1)^{k-|I|} \prod_{j \in J} G^{i,i} \text{ which vanishes as } (-1)^{-|I|} = (-1)^{|J|} = (-1)^{|I,J|-|J|} \text{ and } \sum_{I \supseteq J} (-1)^{|I,J|} = (1-1)^{k-|J|} = 0.
\]

Set \(Q_{k}^{\alpha,\sigma}(u) = P_{k}^{\alpha,\sigma}(u + \alpha \sigma)\) so that \(P_{k}^{\alpha,\sigma}(\tilde{L}_{\alpha}^{-x}) = Q_{k}^{\alpha,\sigma}(\tilde{L}_{\alpha}^{-x})\). This quantity will be called the \(n\)-th renormalized self intersection local time or the \(n\)-th renormalized power of the occupation field and denoted \(\tilde{L}_{\alpha}^{-n}\).

From the recurrence relation of Laguerre polynomials
\[
nL_{n}^{(\alpha-1)}(u) = (-u + 2n + \alpha - 2)L_{n}^{(\alpha-1)} - (n + \alpha - 2)L_{n-2}^{(\alpha-1)},
\]
we get that
\[
nQ_{n}^{\alpha,\sigma}(u) = (u - 2\sigma(n-1))Q_{n-1}^{\alpha,\sigma}(u) - \sigma^{2}(\alpha + n - 2)Q_{n-2}^{\alpha,\sigma}(u).
\]

In particular \(Q_{2}^{\alpha,\sigma}(u) = \frac{1}{2}(u^{2} - 2\sigma u - \alpha \sigma^{2})\), \(Q_{3}^{\alpha,\sigma}(u) = \frac{1}{6}(u^{3} - 6\sigma u^{2} + 3u\sigma^{2}(2 - \alpha) + 4\sigma^{3}\alpha)\).

We have also, from (4.4)
\[
\mathbb{E}(Q_{k}^{\alpha,\sigma_{x}}(\tilde{L}_{\alpha}^{-x}), Q_{l}^{\alpha,\sigma_{y}}(\tilde{L}_{\alpha}^{-y})) = \delta_{k,l}(G^{x,y})^{2k} \frac{Q(\alpha + 1) \ldots (\alpha + k - 1)}{k!} \tag{4.6}
\]

The comparison of the identity (4.6) and corollary 3 yields a combinatorial result which will be extended in the renormalizing procedure presented in the last section.

The identity (4.6) can be considered as a polynomial identity in the variables \(\sigma_{x}, \sigma_{y}\) and \(G^{x,y}\).

Set \(Q_{k}^{\alpha,\sigma}(u) = \sum_{m=0}^{k} q_{m}^{\alpha,k} u^{m} \sigma_{x}^{k-m}\), and denote \(N_{n,m,r,p}\) the number of ordered configurations of \(n\) black points and \(m\) red points on \(r\) non trivial oriented cycles, such that only \(2p\) links are between red and black points. We have first by corollary 3:
\[
\mathbb{E}((\tilde{L}_{\alpha}^{-x})^{n}(\tilde{L}_{\alpha}^{-y})^{m}) = \sum_{r} \sum_{p \leq \min(m,n)} \alpha^{r} N_{n,m,r,p}(G^{x,y})^{2p} (\sigma_{x})^{n-p} (\sigma_{y})^{m-p}
\]
and therefore

\[
\sum_r \sum_{p \leq m, k} \sum_{p \leq n \leq l} \alpha^r q_m^\alpha k q_n^\alpha l N_{n,m,r,p} = 0 \text{ unless } p = l = k.
\] (4.7)

\[
\sum_r \alpha^r q_k^\alpha k q_k^\alpha k N_{k,k,k,k} = \frac{\alpha(\alpha+1)\ldots(\alpha+k-1)}{k!}.
\] (4.8)

Note that one can check directly that \(q_k^\alpha k = \frac{1}{k!}\), and \(N_{k,k,1,k} = k!(k-1)!\), \(N_{k,k,k,k} = k!\) which confirms the identity (4.8) above.

**Exercise 17.** Let \(d_{n,k}^0\) be the number of \(n\)-permutations with no fixed points and \(k\) cycles. If \(k_j, 2 \leq j \leq n\) are integers such that \(\sum_j jk_j = m\) and \(\sum jk_j = k\), let \(C_{m,k}(k_j, 2 \leq j \leq n)\) be the number of \(m\)-permutations with no fixed points and \(k_j\) cycles of length \(j\). Note that \(\sum C_{m,k}(k_j, 2 \leq j \leq n) = d_{m,k}^0\).

Show the following identities:

a) \(\sum_0^n \binom{n}{m} d_{m,k}^0 = d_{n,k}\) (the number of \(n\)-permutations with \(k\) cycles).

b) \(C_{m,k}(k_j, 2 \leq j \leq n) = \frac{m!}{\prod_k k_j}\).

c) \(\sum_0^\infty t^m Q_N^{\alpha,\sigma}(u) = e^{\frac{(u+\alpha)}{\sigma}}(1-\frac{\alpha}{\sigma})^\alpha = e^{\frac{tu}{\sigma}}(1+\sum_0^\infty \frac{m!}{(1+\alpha)^m} \frac{t^m}{m!})\) (Hint: Use corollaries 1 and 3 to prove this equality).

d) \(Q_N^{\alpha,\sigma}(u) = \sum_{0 \leq l \leq N} \sum_{k \leq N-l} \sum_{m=1}^l \frac{1}{m!} \alpha^m (1+\alpha)^{-m-l} \sum_{1 \leq k \leq m} d_{m,k}^0 (-\alpha)^k\)

with \(a_{N,l,k} = \frac{\sum_{m=k}^{N-l} (-1)^{N-l-k-m} (N-1)!}{l!(N-l-m)!(m-l)!} d_{m,k}^0\) for \(k \geq 1\), \(a_{N,l,0} = (-1)^{N-l-k-k-l} (N-1)!\), and \(a_{N,0,0} = 0\).

### 4.3 Hitting probabilities

Let us start with some elements of discrete potential theory. Denote by

\[
[H^F]^x_y = \mathbb{P}_x(x_{T_F} = y)
\]

the hitting distribution of \(F\) by the Markov chain starting at \(x\) \((H^F\) is called the balayage or Poisson kernel in Potential theory). Set \(D = F^c\) and denote by \(e^D, P^D = P|_{D \times D}, V^D = [(I-P^D)]^{-1}\) and \(G^D = [(M^\lambda - C)|_{D \times D}]^{-1}\) the energy, the transition matrix, the potential and the Green function of the Markov chain killed at the hitting time of \(F\).

Denote by \(P^D\) the law of the killed Markov chain starting at \(x\).

Hitting probabilities can be expressed in terms of Green functions. For \(y \in F\), we have

\[
[H^F]^x_y = 1\{x=y\} + \sum_0^\infty \sum_{z \in D} [(P^D)^k]_x z P^z_y
\]
We see also that
\[ V = V^D + H^F V \]
and that
\[ G = G^D + H^F G \]
As \( G \) and \( G^D \) are symmetric, we have \( [H^F G]^z_y = [H^F G]^y_z \) so that for any measure \( \nu \),
\[ H^F(G\nu) = G(\nu H^F). \]
In particular, the capacity potential \( H^F 1 \) is the potential of the capacity measure \( \kappa H^F \).
Therefore we see that for any function \( f \) and measure \( \nu \),
\[ e(H^F f, G^D \nu) = e(H^F f, G\nu) - e(H^F f, H^F G\nu) = \langle H^F f, \nu \rangle - e(H^F f, G(H^F \nu)) = 0 \]
as \( (H^F)^2 = H^F \).
Equivalently, we have the following:

**Proposition 17.** For any \( g \) vanishing on \( F \), \( e(H^F f, g) = 0 \) so that \( I - H^F \) is the \( e \)-orthogonal projection on the space of functions supported in \( D \).

The energy of the capacitary potential of \( F \), \( e(H^F 1, H^F 1) \) equals the mass of the capacitary measure \( \langle \kappa H^F, 1 \rangle \). It is called the capacity of \( F \) and denoted \( Cap_e(F) \).

Note that some of these results extend without difficulty to the recurrent case. In particular, for any measure \( \nu \) supported in \( D \), \( G^D \nu = G(\nu - \nu H^F) \) and \( e(H^F f, G^D \nu) = 0 \) for all \( f \). For further developments see for example ([24]) and its references.

The restriction property holds for \( \mathcal{L}_\alpha \) as it holds for \( \mu \). The set \( \mathcal{L}_\alpha^D \) of loops inside \( D \) is associated with \( \mu^D \) and is independent of \( \mathcal{L}_\alpha \). Therefore, we see from corollary 1 that
\[ \mathbb{E}(e^{\langle \mathcal{L}_\alpha - \mathcal{L}_\alpha^D \times \chi \rangle}) = \left( \frac{\det(G_\chi) \det(G^D)}{\det(G) \det(G^D)} \right)^\alpha. \]

Note that for all \( x \), \( \mu(\tilde{F} > 0) = \infty \). This is due to trivial loops and it can be seen directly from the definition of \( \mu \) that in this simple framework the loops of \( \mathcal{L}_\alpha \) cover the whole space \( X \).

Note however that
\[
\mu(\tilde{F} > 0, p > 1) = \mu(p > 1) - \mu(\tilde{F} = 0, p > 1) = \mu(p > 1) - \mu^D(p > 1)
= -\log\left(\frac{\det(I - P)}{\det_{D \times D}(I - F)}\right) = -\log\left(\frac{\det(G^D)}{\prod_{x \in F} \lambda_x \det(G)}\right).
\]
It follows that the probability that no non trivial loop (i.e. a loop which is not reduced to a point) in $L_\alpha$ intersects $F$ equals

$$\exp(-\alpha \mu(\{l, p(l) > 1, \hat{l}(F) > 0\})) = \left(\frac{\det(G_D)}{\prod_{x \in F} \lambda_x \det(G)}\right)^\alpha.$$  

Recall Jacobi’s identity: for any $(n+p, n+p)$ invertible matrix $A$, denoting $e_i$ the canonical basis,

$$\det(A^{-1}) \det(A_{ij}, 1 \leq i, j \leq n) = \det(A^{-1}) \det(Ae_1, ..., Ae_n, e_{n+1}, ..., e_{n+p})$$

$$= \det(e_1, ..., e_n, A^{-1}e_{n+1}, ..., A^{-1}e_{n+p})$$

$$= \det((A^{-1})_{k,l}, n \leq k, l \leq n+p).$$

In particular, $\det(G_D) = \frac{\det(G)}{\det(G_{F \times F})}$, we can also denote $\frac{\det(G)}{\det(G_{F \times F})}$. So we have the

**Proposition 18.** The probability that no non-trivial loop in $L_\alpha$ intersects $F$ equals

$$[\prod_{x \in F} \lambda_x \det(G)]^{-\alpha}.$$  

Moreover $E(e^{-\left(\frac{\det(G)}{\det(G_{F \times F})}\right)}) = \left(\frac{\det(G)_{F \times F}}{\det(G)}\right)^\alpha$.

In particular, it follows that the probability that no non-trivial loop in $L_\alpha$ visits $x$ equals $(\frac{1}{\lambda_x G^x})^\alpha$ which is also a consequence of the fact that $N_x$ follows a negative binomial distribution of parameters $-\alpha$ and $\frac{1}{\lambda_x G^x}$.

Also, if $F_1$ and $F_2$ are disjoint,

$$\mu(\hat{l}(F_1) \cap \hat{l}(F_2) > 0) = \mu(\hat{l}(F_1) > 0, p > 1) + \mu(\hat{l}(F_2) > 0, p > 1) - \mu(\hat{l}(F_1 \cup F_2) > 0, p > 1)$$

(4.9)  

$$= \log(\frac{\det(G) \det(G_{D_1 \cap D_2})}{\det(G_D) \det(G_{D_1 \cap D_2})}) = \log(\frac{\det(F_1 \times F_1(G) \det(F_2 \times F_2(G))}{\det(F_1 \cup F_2 \times F_1 \cup F_2(G))}).$$

Therefore the probability that no loop in $L_\alpha$ intersects $F_1$ and $F_2$ equals

$$\exp(-\alpha \mu(\{l, \prod_{x \in F} \hat{l}(F_i) > 0\})) = \left(\frac{\det(G_{D_1}) \det(G_{D_2})}{\det(G_D) \det(G_{D_1 \cap D_2})}\right)^\alpha = \left(\frac{\det(F_1 \times F_1(G) \det(F_2 \times F_2(G))}{\det(F_1 \cup F_2 \times F_1 \cup F_2(G))}\right)^{-\alpha}$$

It follows that the probability no loop in $L_\alpha$ visits two distinct points $x$ and $y$ equals $(\frac{G_{x,y}^2}{G_{x-x}G_{y-y} - (G_{x-y})^2})^\alpha$ and in particular $1 - (\frac{G_{x-y}^2}{G_{x-x}G_{y-y} - (G_{x-y})^2})^\alpha$ if $\alpha = 1$.

**Exercise 18.** Generalize this formula to $n$ disjoint sets:

$$\mathbb{P}(\forall l \in L_\alpha, \prod_{x \in F} \hat{l}(F_i) > 0) = \left(\frac{\det(G) \prod_{i<j} \det(G_{D_i \cap D_j})}{\prod \det(G_{D_i}) \prod_{i<j<k} \det(G_{D_i \cap D_j \cap D_k})}\right)^{-\alpha}$$

Note this yields an interesting determinant product inequality.
Chapter 5
The Gaussian free field

5.1 Dynkin’s Isomorphism

By a well known calculation on Gaussian measure, if $X$ is finite, for any $\chi \in \mathbb{R}^X_+$,

$$
\frac{\sqrt{\det(M_\chi - C)}}{(2\pi)^{\frac{|X|}{2}}} \int_{\mathbb{R}^X} e^{-\frac{1}{2} \sum \chi_u(v^u)^2} e^{-\frac{1}{2} c(v)} \Pi_{u \in X} dv^u = \sqrt{\frac{\det(G_\chi)}{\det(G)}}
$$

and

$$
\frac{\sqrt{\det(M_\chi - C)}}{(2\pi)^{\frac{|X|}{2}}} \int_{\mathbb{R}^X} v^x v^y e^{-\frac{1}{2} \sum \chi_u(v^u)^2} e^{-\frac{1}{2} c(v)} \Pi_{u \in X} dv^u = (G_\chi)^{x,y} \sqrt{\frac{\det(G_\chi)}{\det(G)}}
$$

This can be easily reformulated by introducing on an independent probability space the Gaussian free field $\phi$ defined by the covariance $E_\phi(\phi^x \phi^y) = G^x,y$ (this reformulation cannot be dispensed when $X$ becomes infinite).

So we have

$$
E_\phi(e^{-\frac{1}{2} \langle \phi^2, \chi \rangle}) = \det(I + GM_\chi)^{-\frac{1}{2}} = \sqrt{\det(G_\chi G^{-1})}
$$

and

$$
E_\phi(\phi^x \phi^y e^{-\frac{1}{2} \langle \phi^2, \chi \rangle}) = (G_\chi)^{x,y} \sqrt{\det(G_\chi G^{-1})}.
$$

Then since sums of exponentials of the form $e^{-\frac{1}{2} \langle \cdot, \chi \rangle}$ are dense in continuous functions on $\mathbb{R}^X_+$ the following holds:

**Theorem 2.** a) The fields $\hat{\mathcal{L}}_\phi$ and $\frac{1}{2} \phi^2$ have the same distribution.

b) $E_\phi((\phi^x \phi^y F(\frac{1}{2} \phi^2))) = \int E(F(\hat{\mathcal{L}}_\phi + \gamma)) \mu^{\chi,y}(d\gamma)$ for any bounded functional $F$ of a non-negative field.

**Remarks:**

a) This can be viewed as a version of Dynkin’s isomorphism (Cf [8]). It can be extended to non-symmetric generators (Cf [26]).
b) For \( x = y \), b) follows from a) and corollary 2. Also, by the same corollary if \( C_{x,y} \neq 0 \), b) implies that

\[
\mathbb{E}_\phi (\phi^x \phi^y F(\frac{1}{2} \phi^2)) = \frac{2}{C_{x,y}} \mathbb{E}(F(\widehat{L}_k) N_{x,y})
\]

c) An analogous result can be given when \( \alpha \) is any positive half integer, by using real vector valued Gaussian field, or equivalently complex fields for integral values of \( \alpha \) (in particular \( \alpha = 1 \)): If \( \phi = (\phi_1, \phi_2, ..., \phi_k) \) are \( k \) independent copies of the real free field, the fields \( \widehat{L}_k \) and \( \frac{1}{2} \|\phi\|^2 = \frac{1}{2} \sum \phi_j^2 \) have the same law and

\[
\mathbb{E}_\phi (\langle \phi^x, \phi^y \rangle F(\frac{1}{2} \|\phi\|^2)) = k \int \mathbb{E}(F(\widehat{L}_k + \widehat{\gamma})) \mu^{x,y}(d\gamma)
\]

The complex free field \( \phi_1 + i\phi_2 \) will be denoted \( \varphi \). If we consider \( k \) independent copies \( \varphi_j \) of this field, \( \widehat{L}_k \) and \( \frac{1}{2} \|\varphi\|^2 = \frac{1}{2} \sum \varphi_j \varphi_j^* \) have the same law.

d) Note it implies immediately that the process \( \phi^2 \) is infinitely divisible. See [11] and its references for a converse and earlier proofs of this last fact.

Theorem 2 suggests the following:

**Exercise 19.** Show that for any bounded functional \( F \) of a non negative field, if \( x_i \) are \( 2k \) points:

\[
\mathbb{E}_\phi (F(\phi^2) \prod \phi^{x_i}) = \int \mathbb{E}(F(\widehat{L}_k + \sum \gamma_j)) \prod \mu^{y_j, z_j}(d\gamma_j)
\]

where \( \sum \text{pairings} \) means that the \( k \) pairs \( y_j, z_j \) are formed with all the \( 2k \) points \( x_i \), in all \( \frac{(2k)!}{(2k^2)} \) possible ways.

Hint: As in the proof of theorem 2, we take \( F \) of the form \( e^{-\frac{1}{2} \langle \cdot, \phi \rangle} \). Then we use the classical expression for the expectation of a product of Gaussian variables known as Wick theorem (see for example [37], [50]).

**Exercise 20.** For any \( f \) in the Dirichlet space \( H \) of functions of finite energy (i.e. for all functions if \( X \) is finite), the law of \( f + \phi \) is absolutely continuous with respect to the law of \( \phi \), with density \( \exp(\langle -L f, \phi \rangle_m - \frac{1}{2}\epsilon(f)) \).

**Exercise 21.** a) Using proposition 17, show (it was observed by Nelson in the context of the classical (or Brownian) free field) that the Gaussian field \( \phi \) is Markovian: Given any subset \( F \) of \( X \), denote \( \mathcal{H}_F \) the Gaussian space spanned by \( \{ \phi^y, y \in F \} \). Then, for \( x \in D = F^c \), the projection of \( \phi^x \) on \( \mathcal{H}_F \) (i.e. the conditional expectation of \( \phi^x \) given \( \sigma(\phi^y, y \in F) \)) is \( \sum_{y \in F} [H^F]_y^* \phi^y \).
5.2 Wick products

We have seen in theorem 2 that $L^2$ functionals of $\hat{\mathcal{L}}_1$ can be represented in this space of Gaussian functionals. In order to prepare the extension of this representation to the more difficult framework of continuous spaces (which can often be viewed as scaling limits of discrete spaces), including especially the planar Brownian motion considered in [20], we shall introduce the renormalized (or Wick) powers of $\phi$. We set:

$$\phi_x^n := (\hat{\mathcal{L}}_1^* x^n \hat{\mathcal{L}}_1)^{\frac{1}{2}} H_n(\frac{x}{\sqrt{\hat{\mathcal{L}}_1^* x^n \hat{\mathcal{L}}_1}})$$

where $H_n$ is the $n$-th Hermite polynomial (characterized by $\sum t^n n! H_n(u) = e^{tu - t^2}$). These variables are orthogonal in $L^2$ and $E((\phi_x^n)^2) = n! G_{x,x}$. 

More generally, if $\phi_1, \phi_2, \ldots, \phi_k$ are $k$ independent copies of the free field, we can define:

$$\Pi_{j=1}^k (\phi_x^n) : = \prod_{j=1}^k (\phi_x^n) : \text{ Then it follows that:}$$

$$\sum_{n_1 + \ldots + n_k = n} \frac{n!}{n_1! \ldots n_k!} \prod_{j=1}^k (\phi_{x_j}^{2n_j}) :$$

On the other hand, from the generating function of the polynomials $P_n^{\phi,\sigma}$, we get easily that

$$P_n^{\phi,\sigma}(\sum_{j=1}^k u_{x_j}) = \sum_{n_1 + \ldots + n_k = n} \prod_{j=1}^k P_n^{\phi,\sigma}(u_{x_j}).$$

Therefore,

$$P_n^{\phi,\sigma}(\sum_{j=1}^k (\phi_{x_j}^2) = \frac{1}{2 \sigma^2 n!} : (\sum_{j=1}^k (\phi_{x_j}^2)^n :.$$ (5.1)

Note that in particular, $: \sum_{j=1}^k (\phi_{x_j}^2) :$ equals $(\phi_{x_j}^2 - \sigma^x$. These variables are orthogonal in $L^2$. Let $\tilde{t}^x = t^x - \sigma^x$ be the centered occupation field. Note that
an equivalent formulation of theorem 2 is that the fields \( \frac{1}{2} \sum_{j=1}^{k} \varphi_{x_{j}}^{2} \) and \( \tilde{L}_{\frac{1}{2}} \) have the same law.

If we use complex fields \( P_{\alpha}^{n} = \frac{1}{\sqrt{n!}} \left( \varphi_{x_{j}}^{2} \right)^{n} \).

Let us now consider the relation of higher Wick powers with self intersection local times.

Recall that the renormalized \( n \)-th self intersections field \( \tilde{L}_{\alpha,x}^{n} = P_{\alpha}^{n} = Q_{\alpha,x}^{n} \) have been defined by orthonormalization in \( L^{2} \) of the powers of the occupation time.

Then comes the

**Proposition 19.** a) The fields \( \tilde{L}_{\frac{1}{2}}^{n} \) and \( \frac{1}{n!2^{n/n}} \left( \sum_{j=1}^{k} \varphi_{x_{j}}^{2} \right)^{n} \) have the same law.

In particular \( \tilde{L}_{\frac{1}{2}}^{n} \) and \( \frac{1}{n!2^{n/n}} \left( \sum_{j=1}^{k} \varphi_{x_{j}}^{2} \right)^{n} \) have the same law.

This follows directly from (5.1).

**Remark 8.** As a consequence, we obtain from 4.6 and 5.1 that:

\[
\frac{k(k+2)...(k+2(n-1))}{2^n n!} = \sum_{n_1+...+n_k=n} \prod_{i=1}^{k} \frac{2n_i!}{(2^{n_i} n_i !)^2} \quad (5.2)
\]

Moreover, it can be shown that:

\[
\mathbb{E}(\prod_{j=1}^{r} Q_{k_j}^{\alpha,x_{j}}(\tilde{L}_{\alpha}^{x_{j}})) = \sum_{\sigma \in S_{k_1,k_2,...,k_j}} \alpha^{m(\sigma)} G^{y_{1},y_{\sigma(1)}} ... G^{y_{k},y_{\sigma(k)}}
\]

\( y_{i} = x_{j} \) for \( \sum_{i=1}^{j-1} k_{l} + 1 \leq i \leq \sum_{i=1}^{j} k_{l} + k_{j} \) and where \( S_{k_1,k_2,...,k_j} \) denotes the set of permutations \( \sigma \) of \( k = \sum_{j} k_{j} \) such that

\( \sigma(\{\sum_{i=1}^{j-1} k_{l} + 1, ... \sum_{i=1}^{j-1} k_{l} + k_{j}\}) \cap \{\sum_{i=1}^{j-1} k_{l} + 1, ... \sum_{i=1}^{j-1} k_{l} + k_{j}\} \) is empty for all \( j \).

The identity follows from Wick’s theorem when \( \alpha \) is an integer, then extends to all \( \alpha \) since both members are polynomials in \( \alpha \). The condition on \( \sigma \) indicates that no pairing is allowed inside the same Wick power. For the proof, one can view each term of the form : \( (\varphi_{x_{j}}^{2} \overline{\varphi}_{x_{j}}^{2})^{k} \) as the product of \( k \) distinct pairs, in a given order, then the pairings between \( \varphi \)’s and \( \overline{\varphi} \)’s are defined by an element of \( S_{k_1,k_2,...,k_j} \) and a system of permutations of \( S_{k_1},...S_{k_j} \).

This system of permutations produces multiplicities that cancel with the \( \frac{1}{n!} \) factors in the expression. Note finally that \( \mathbb{E}(\varphi_{x_{j}}^{2} \overline{\varphi}_{x_{j}}^{2}) = 2G^{x,y} \) to cancel the \( 2^{-k_{j}} \) factors.
5.3 The Gaussian Fock space structure

The Gaussian space \( \mathcal{H} \) spanned by \( \{ \phi^x, x \in X \} \) is isomorphic to the dual of the Dirichlet space \( \mathbb{H}^* \) by the linear map mapping \( \phi^x \) on \( \delta_x \). This isomorphism extends into an isomorphism between the space of square integrable functionals of the Gaussian field and the real symmetric Fock space \( \Gamma \circ (\mathbb{H}^*) = \bigoplus \mathbb{H}^{* \otimes n} \) obtained as the closure of the sum of all symmetric tensor powers of \( \mathbb{H}^* \) (the zero-th tensor power is \( \mathbb{R} \)). In the case of discrete spaces, these symmetric tensor powers can be represented simply as symmetric signed measures on \( X^n \) (with no additional constraint in the finite space case). In terms of the ordinary tensor product \( \otimes \), the symmetric tensor product \( \mu_1 \otimes \cdots \otimes \mu_n \) is defined as \( \frac{1}{\sqrt{n!}} \sum_{\sigma \in S_n} \mu_{\sigma(1)} \otimes \cdots \otimes \mu_{\sigma(n)} \) so that in particular, \( \| \mu \|_2^2 = n! \left( \sum G^{xy} \mu_x \mu_y \right)^n \). The construction of \( \Gamma (\mathbb{H}^*) \) is known as Bose second quantization. The isomorphism mentioned above is defined by the following identification, done for any \( \mu \) in \( \mathbb{H}^* \):

\[
\exp \circ (\mu) \leftrightarrow \exp \left( \sum_x \phi^x \mu_x - \frac{1}{2} \sum_{x,y} G^{xy} \mu_x \mu_y \right)
\]

which is an isometry as

\[
\mathbb{E} \phi (\exp \left( \sum_x \phi^x \mu_x - \frac{1}{2} \sum_{x,y} G^{xy} \mu_x \mu_y \right) \exp \left( \sum_x \phi^x \mu'_x - \frac{1}{2} \sum_{x,y} G^{xy} \mu'_x \mu'_y \right)) \exp (\exp (\exp \left( - \sum_{x,y} G^{xy} \mu_x \mu_y \right)) = \exp (\sum_{x,y} G^{xy} \mu_x \mu_y))
\]

The proof is completed by observing that linear combination of

\[
\exp \left( \sum_x \phi^x \mu_x - \frac{1}{2} \sum_{x,y} G^{xy} \mu_x \mu_y \right)
\]

form a dense algebra in the space of square integrable functionals of the Gaussian field.

The \( n \)-th Wick power \( (\phi^x)^n \) is the image of the \( n \)-th symmetric tensor power \( \delta_x \otimes^n \). More generally, for any \( \mu \) in \( \mathbb{H}^* \), \( (\sum_x \phi^x \mu_x)^n \) is the image of the \( n \)-th symmetric tensor power \( \mu \otimes^n \). Therefore, \( \phi^{x_1} \phi^{x_2} \cdots \phi^{x_n} \) is the image of \( \delta_{x_1} + \cdots + \delta_{x_n} \), and polynomials of the field are associated with the non completed Fock space \( \bigoplus \mathbb{H}^{* \otimes n} \).

For any \( x \in X \), the anihilation operator \( a_x \) and the creation operator \( a_x^* \) are defined as follows, on the uncompleted Fock space \( \bigoplus \mathbb{H}^{* \otimes n} \):

\[
a_x (\mu_1 \otimes \cdots \otimes \mu_n) = \sum_k G \mu_k(x) \mu_1 \otimes \cdots \otimes \mu_{k-1} \otimes \mu_{k+1} \otimes \cdots \otimes \mu_n
\]

\[
a_x^* (\mu_1 \otimes \cdots \otimes \mu_n) = \delta_x \otimes \mu_1 \otimes \cdots \otimes \mu_n.
\]
Moreover, we set \( a_x 1 = 0 \) for all \( x \). These operator \( a_x \) and \( a_x^* \) are clearly dual of each other and verify the commutation relations:

\[
[a_x, a_y^*] = G^{x,y} \quad [a_y^*, a_x^*] = [a_x, a_y] = 0.
\]

The isomorphism allows to represent them on polynomials of the field as follows:

\[
a_x \leftrightarrow \sum_y G^{x,y} \frac{\partial}{\partial \phi^y}, \quad a_x^* \leftrightarrow \phi_x - \sum_y G^{x,y} \frac{\partial}{\partial \phi^y}
\]

Therefore, the Fock space structure is entirely transported on the space of square integrable functionals of the free field.

In the case of a complex field \( \varphi \), the space of square integrable functionals of \( \varphi \) and \( \overline{\varphi} \) is isomorphic to the symmetric tensor product of two copies of the symmetric Fock space \( \Gamma^\otimes(\mathbb{H}^*) \), we will denote by \( \mathcal{F}_B \). It is isomorphic to \( \Gamma^\otimes(\mathbb{H}_1^* + \mathbb{H}_2^*) \), \( \mathbb{H}_1 \) and \( \mathbb{H}_2 \) being two copies of \( \mathbb{H} \). The complex Fock space structure is defined by two commuting sets of creation and anihilation operators:

\[
a_x = \sqrt{2} \sum_y G^{x,y} \frac{\partial}{\partial \varphi^y} \quad a_x^* = \frac{\varphi_x}{\sqrt{2}} - \sqrt{2} \sum_y G^{x,y} \frac{\partial}{\partial \overline{\varphi^y}}
\]

\[
b_x = \sqrt{2} \sum_y G^{x,y} \frac{\partial}{\partial \overline{\varphi^y}} \quad b_x^* = \frac{\overline{\varphi}_x}{\sqrt{2}} - \sqrt{2} \sum_y G^{x,y} \frac{\partial}{\partial \varphi^y}
\]

(Recall that if \( z = x + iy \), \( \frac{\partial}{\partial z} = \frac{\partial}{\partial x} - i \frac{\partial}{\partial y} \) and \( \frac{\partial}{\partial \overline{z}} = \frac{\partial}{\partial x} + i \frac{\partial}{\partial y} \)).

We have

\[
\varphi^x = \sqrt{2}(b_x + a_x^*) \quad \overline{\varphi}^x = \sqrt{2}(a_x + b_x^*)
\]

See [50], [37] for a more general description of this isomorphism.

**Exercise 22.** Let \( A \) and \( B \) be two polynomials in \( \varphi \) and \( \overline{\varphi} \), identified with finite degree element in \( \mathcal{F}_B \). Show by recurrence on the degrees that

\[
AB = \sum \frac{1}{p!} \gamma_p(A, B) \quad \text{with} \quad \gamma_0(A, B) = A \otimes B \quad \text{and} \quad \gamma_{p+1}(A, B) = \sum_x (\gamma_p(a_x A, b_x B) + \gamma_p(b_x A, a_x B)).
\]

### 5.4 The Poissonian Fock space structure

Another symmetric Fock space structure is defined on the spaces of \( L^2 \)-functional of the loop ensemble \( \mathcal{L} \mathcal{P} \). It is based on the space \( h = L^2(\mu^L) \) where \( \mu^L \) denotes \( \mu \otimes \text{Leb} \). For any \( G \in L^2(\mu^L) \) define
5.4 The Poissonian Fock space structure

\[ G_0(t, l) = G(t, l)\mathbf{1}_{\{T(l) > \varepsilon\}}\mathbf{1}_{\{|t| < \frac{1}{\varepsilon}\}} \]

Note that \( G_0 \) is always integrable. Define

\[ \mathfrak{h}_0 = \bigcup_{\varepsilon > 0} \{ G \in L^\infty(\mu^L), \exists \varepsilon > 0, G = G_\varepsilon \text{ and } \int G d\mu^L = 0\}. \]

The algebra \( \mathfrak{h}_0 \) is dense in \( L^2(\mu^L) \) (as, for example, compactly supported square integrable functions with zero integral are dense in \( L^2(Leb) \)).

Given any \( F \) in \( \mathfrak{h}_0 \), \( L^2(\mu^L) = \sum_{t_i \in \mathcal{L}^F} \left\{ G_{\sigma}(j) \right\} \) is well defined and \( \mathbb{E}(L^2(\mu^L)^2) = \langle F, F \rangle_{L^2(\mu^L)} \). By Stone-Weierstrass theorem, the algebra generated by \( \mathcal{L}^F(\mathfrak{h}_0) \) is dense in \( L^2(\mu^L) \).

By Campbell formula, the \( n \)-th chaos, isomorphic to the symmetric tensor product \( \mathfrak{h}_0 \otimes^n \), can be defined as the closure of the linear span of functions of \( n \) distinct points of \( L^2(\mu^L) \) of the form

\[ \sum_{\sigma \in \mathcal{S}_n} \prod_{1}^{n} G_{\sigma(j)}(l_j, t_j) \]

with \( G_j \) in \( \mathfrak{h}_0 \).

Denote by \( \mathcal{L}^F \) the jump times of the Poisson process \( \mathcal{L}^F \). It follows directly from formula (4.2) that for

\[ \Phi = \frac{1}{\sqrt{n!}} \sum_{\sigma \in \mathcal{S}_n} \prod_{1}^{n} G_{\sigma(j)}(l_j, t_j) \text{ and } \Phi' \]

\[ = \frac{1}{\sqrt{n!}} \sum_{\sigma \in \mathcal{S}_n} \prod_{1}^{n} G_{\sigma(j')}(l'_j, t'_j) \]

with \( G_j, G'_j \) in \( \mathfrak{h}_0 \),

\[ \mathbb{E}(\Phi\Phi') = 1_{\{n=n'\}} \text{Per}(\langle G_j, G'_j \rangle_{L^2(\mu^L)}), 1 \leq j, j' \leq n \]

which equals \( 1_{\{n=n'\}} \langle G_1 \circ G_2 \cdots \circ G_n, G'_1 \circ G'_2 \cdots \circ G'_{n'} \rangle, \circ \) denoting the symmetric tensor product (Cf. [4], [37]).

This proves the existence of an isomorphism \( \text{Iso} \) between the algebra generated by \( \mathcal{L}^F(\mathfrak{h}_0) \) and the tensor algebra \( \oplus_{\mathfrak{h}_0} \mathfrak{h}_0 \otimes^n \) which extends into an isomorphism between the space \( L^2(\mathcal{P}^{\mathcal{L}^F}) \) of square integrable functionals of the Poisson process of loops \( \mathcal{L}^F \) and the symmetric (or bosonic) Fock space \( \oplus_{\mathfrak{h}_0} \mathfrak{h}_0 \otimes^n \).

We have

\[ \text{Iso}(\frac{1}{\sqrt{n!}} \sum_{\sigma \in \mathcal{S}_n} \prod_{1}^{n} G_{\sigma(j)}(l_j, t_j)) = G_1 \circ G_2 \circ \cdots \circ G_n. \]
This formula extends to \( G_i \in \mathfrak{h} \). The closure of the space that functionals of this form generate linearly is by definition the n-th chaos which is isomorphic to the symmetric tensor product \( \mathfrak{h}^{\otimes n} \).

Note that for any \( G \) in \( \mathfrak{h}_0 \), the image by this isomorphism \( \text{Iso} \) of the tensor exponential \( \exp^\mathfrak{h}(G) \) is \( \prod_{l_i \in \mathcal{LP}} (1 + G(l_i, t_i)) \).

Note also that for all \( F \) in \( \mathfrak{h} \), \( \| \exp^\mathfrak{h}(F) \|_2^2 = e^{\int F^2 d\mu_L} \).

**Proposition 20.** For any \( F \) in \( \mathfrak{h} \), the image by \( \text{Iso} \) of the tensor exponential \( \exp^\mathfrak{h}(F) \) is obtained as the limit in \( L^2 \), as \( \varepsilon \to 0 \) of

\[
\prod_{l_i \in \mathcal{LP}} (1 + F(\varepsilon)(l_i, t_i)) e^{-\int F(\varepsilon) d\mu_L}.
\]

**Proof.** Note first that

\[
\mathbb{E}\left( \prod_{t_i \in \mathcal{LP}} (1 + F(\varepsilon)(l_i, t_i)) e^{-\int F(\varepsilon) d\mu_L} \right) = 1
\]

and

\[
\mathbb{E}\left( \prod_{t_i \in \mathcal{LP}} (1 + F(\varepsilon)(l_i, t_i)) e^{-\int F(\varepsilon) d\mu_L} \right)^2
\]

\[
= \exp\left( \int (1 + F(\varepsilon))^2 - 1 \right) \mu_L e^{-2 \int F(\varepsilon) d\mu_L} = \exp\left( \int F^2(\varepsilon) d\mu_L \right)
\]

converges towards \( \exp(\int F^2 d\mu_L) \).

Then note that for any \( G \) in \( \mathfrak{h}_0 \),

\[
\lim_{\varepsilon \to 0} \mathbb{E}\left( \prod_{l_i \in \mathcal{LP}} (1 + G(l_i, t_i)(1 + F(\varepsilon)(l_i, t_i)) e^{-\int F(\varepsilon) d\mu_L} \right)
\]

\[
= \lim_{\varepsilon \to 0} \exp\left( \int (1 + G)[1 + F(\varepsilon)] - 1 \right) \mu_L e^{-2 \int F(\varepsilon) d\mu_L} = \exp\left( \int (FG)_\varepsilon d\mu_L \right)
\]

\[
= \exp(\int FG d\mu_L) = \langle \exp^\mathfrak{h}(F), \exp^\mathfrak{h}(G) \rangle.
\]

**Exercise 23.** For any \( F \) in \( \mathfrak{h} \), set \( F_{\leq \alpha}(l, t) = F(l, t)1_{\{t \leq \alpha\}} \). Show that \( \text{Iso}(\exp^\mathfrak{h}(F_{\leq \alpha})) \) is a \( \sigma(L_\alpha) \)-martingale.

Prove that the \( \sigma(L_\alpha) \)-martingale \( (1 + \sigma_Z t)^{\alpha} \exp(\frac{\sigma_Z}{1 + \sigma_Z t}) \) is in this way associated with \( F(l, t) = e^{\frac{\sigma_Z}{1 + \sigma_Z t}} - 1 \).

Deduce from this an expression of \( P^{\alpha, \sigma_Z}(\widehat{L}_\alpha^x) \) in terms of \( \sigma_Z^k D_{k_i} (\widehat{L}_\alpha^x) \) (the polynomials defined in section 2.4), \( l_i \) denoting distinct loops in \( L_\alpha \) and \( k_i \) positive integers less than \( k \).

For any \( G \) in \( \mathfrak{h}_0 \), unbounded annihilation and creation operators \( \mathfrak{A}_G \) and \( \mathfrak{A}^*_G \) are defined on \( \otimes \mathfrak{h}^{\otimes n} \).
5.4 The Poissonian Fock space structure

\[ \mathfrak{A}_G(G_1 \odot \ldots \odot G_n) = \sum_{k=1}^{n} (G, G_k)_\mathfrak{h} G_1 \odot \ldots G_{k-1} \odot G_{k+1} \ldots \odot G_n \]

and

\[ \mathfrak{A}_G^*(G_1 \odot \ldots \odot G_n) = G \odot G_1 \odot \ldots \odot G_n \]

Note that

\[ [\mathfrak{A}_G^*, \mathfrak{A}_F^*] = [\mathfrak{A}_G, \mathfrak{A}_F^*] = 0 \]

\[ [\mathfrak{A}_G, \mathfrak{A}_F^*] = \langle F, G \rangle_{L^2(\mu_L)} \]

Moreover, \( \mathfrak{A}_G^* \) is adjoint to \( \mathfrak{A}_G \) in \( L^2(P_L\mathcal{P}) \), and the operators \( \mathfrak{F}_G = \mathfrak{A}_G^* + \mathfrak{A}_G \) commute.

Note also that the creation operator can be defined directly on the space of loop configurations: by proposition 15 given any bounded functional \( \Psi \) on loops configurations,

\[ Iso \mathfrak{A}_G^* Iso^{-1}\Psi(P_L) = \int \Psi(P_L \cup \{l, t\})G(l, t)d\mu^L \]

It is enough to verify it for \( Iso^{-1}\Psi \) in \( \mathfrak{h}_0^{\odot n} \).

For any \( G \) in \( \mathfrak{h}_0 \cap L^\infty \), note that \( \mathfrak{F}_G \) does not represent the multiplication by \( \mathcal{P}(G) \), though we have, for all \( \Phi \) in \( \oplus \mathfrak{h}^{\odot n} \) and \( G \) in \( \mathfrak{h}_0 \),

\[ E(Iso(F)\mathcal{P}(G)) = \langle \mathfrak{F}_G 1, \Phi \rangle = \langle 1, \mathfrak{F}_G \Phi \rangle. \]

The representation of this operator of multiplication in the Fock space structure can be done as follows:

Setting \( M_GF = GF \), for all \( \Phi \) in \( \oplus \mathfrak{h}^{\odot n} \)

\[ \left( \sum_{t, i \in \mathcal{P}} G(l_i, t_i)Iso(\Phi) = Iso(\mathfrak{F}_G \Phi + d\Gamma(M_G)). \right) \]

The notation \( d\Gamma \) refers to the second quantisation functor \( \Gamma \); if \( B \) is any bounded operator on a Hilbert space \( \mathfrak{h} \), \( \Gamma(B) \) is defined on \( \oplus \mathfrak{h}^{\odot n} \) by the sum of the operators \( B^{\odot n} \) acting on each symmetric tensor product \( \mathfrak{h}^{\odot n} \) and

\[ d\Gamma(B) = \frac{\partial}{\partial t} \Gamma(e^{tB})|_{t=0}. \]

In fact, given any orthonormal basis \( E_k \) of \( \mathfrak{h} \), we have, for any \( \Phi \) in \( \oplus \mathfrak{h}^{\odot n} \) and \( G \) in \( \mathfrak{h} \)

\[ d\Gamma(B) = \sum \mathfrak{A}^*_B E_k \mathfrak{A} E_k = \sum \mathfrak{A}^*_E_k \mathfrak{A} B^* E_k \]

as

\[ \sum \langle F, E_k \rangle_{L^2(\mu_L)}(BE_k) = \sum \langle F, BE_k \rangle_{L^2(\mu_L)} E_k = BF. \]
Chapter 6
Energy variation and representations

6.1 Variation of the energy form

The loop measure $\mu$ depends on the energy $e$ which is defined by the free parameters $C, \kappa$. We shall denote $Z_e$ the determinant $\det(G) = \det(M_\lambda - C)^{-1}$. Then $\mu(p > 1) = \log(Z_e) + \sum_{x \in X} \log(\lambda_x)$.

$Z_e$ is called the partition function of $\mathcal{L}_\alpha$.

We wish to study the dependance of $\mu$ on $C$ and $\kappa$. The following result is suggested by an analogy with quantum field theory (Cf [13]).

Proposition 21. i) $\frac{\partial \mu}{\partial \kappa_x} = -\hat{l}_x \mu$.
ii) If $C_{x,y} > 0$, $\frac{\partial \mu}{\partial C_{x,y}} = -T_{x,y} \mu$ with $T_{x,y}(l) = (\hat{l}_x + \hat{l}_y) - \frac{N_{x,y}}{C_{x,y}}(l) - \frac{N_{y,x}}{C_{y,x}}(l)$.

Proof. Recall that by formula (2.8): $\mu^*(p = 1, \xi = x, \hat{\tau}_i \in dt_i) = e^{-\lambda_x t} dt$ and

$\mu^*(p = k, \xi_i = x, \hat{\tau}_i \in dt_i) = \frac{1}{k} \prod_{x,y} C_{x,y}^{N_{x,y}} \prod_x \lambda_x^{-N_x} \prod_{i \in \mathbb{Z}/p\mathbb{Z}} \lambda_{\xi_i} e^{-\lambda_{\xi_i} t_i} dt_i$.

Moreover we have $C_{x,y} = C_{y,x}$ and $\lambda_x = \kappa_x + \sum_y C_{x,y}$.

The two formulas follow by elementary calculation.

Recall that $\mu(\hat{l}_x) = G^{x,x}$ and $\mu(N_{x,y}) = G^{x,y}C_{x,y}$. So we have $\mu(T_{x,y}(l)) = G^{x,x} + G^{y,y} - 2G^{x,y}$. Then, the above proposition allows us to compute all moments of $T$ and $\hat{l}$ relative to $\mu_e$ (they could be called Schwinger functions).

Exercise 24. Use the proposition above to show that:

$\int \hat{l}_x \hat{l}_y \mu(dl) = (G^{x,y})^2$

$\int \hat{l}_x T_{y,z}(l)\mu(dl) = (G^{x,y} - G^{x,z})^2$

and

$\int T_{x,y}(l)T_{u,v}(l)\mu(dl) = (G^{x,u} + G^{y,v} - G^{x,v} - G^{y,u})^2 = (K^{(x,y),(u,v)})^2$
Hint: The calculations are done noticing that for any invertible matrix function \( M(s) \), \( \frac{d}{ds} M(s)^{-1} = -M(s)^{-1}M'(s)M(s)^{-1} \). The formula is applied to \( M = M_\lambda - C \) and \( s = \kappa_x \) or \( C_{x,y} \).

**Exercise 25.** Show that \( \int \left( \frac{1}{2} \sum_{x,y} C_{x,y} T^{x,y}(l) + \sum_{x} \kappa_x \tilde{\ell}^x \right) \mu(\text{d}l) = |X| \) and that more generally, for any \( D \subset X \),

\[
\int \left( \frac{1}{2} \sum_{x,y \in D} C_{x,y} T \right) \mu(\text{d}l) + \sum_{x \in D, y \in X - D} C_{x,y} G^{x,y} \]

Set

\[
T^{(a)}_{x,y} = \sum_{l \in L_a} T_{x,y}(l) = (\hat{\mathcal{L}}^x_a + \hat{\mathcal{L}}^y_a) - \frac{N^{(a)}_{x,y}}{C_{x,y}} - \frac{N^{(a)}_{y,x}}{C_{x,y}}
\]

and

\[
\tilde{T}^{(a)}_{x,y} = T^{(a)}_{x,y} - \mathbb{E}(T^{(a)}_{x,y}) = T^{(a)}_{x,y} - \alpha(G^{x.x} + G^{y.y} - 2G^{x,y}).
\]

We can apply proposition 21 to the Poissonian loop ensembles, to get the following

**Corollary 4.** For any bounded functional \( \Phi \) on loop configurations

i) \( \frac{\partial}{\partial \kappa_{x,y}} \mathbb{E}(\Phi(L_a)) = -\mathbb{E}(\Phi(L_a)\tilde{\mathcal{L}}^x_a) = \alpha \int \mathbb{E}((\Phi(L_a) - \Phi(L_a \cup \{\gamma\})) \mu^{x,y}(\text{d}\gamma). \)

ii) If \( C_{x,y} > 0 \),

\[
\frac{\partial}{\partial C_{x,y}} \mathbb{E}(\Phi(L_a)) = -\mathbb{E}(\tilde{T}^{(a)}_{x,y} \Phi(L_a)) = \alpha \int \mathbb{E}((\Phi(L_a) - \Phi(L_a \cup \{\gamma\})) \mu^{x,y}(\text{d}\gamma) \mu^{x,y}(\text{d}\gamma) - \mu^{x,y}(\text{d}\gamma) - \mu^{x,y}(\text{d}\gamma)]
\]

The proof is easily performed, taking first \( \Phi \) of the form \( \sum_{l_1 \neq l_2 \ldots \neq l_q} \prod_{j=1}^q G_j(l_j) \).

We apply Campbell formula to deduce the first half of both identities, then corollary 2 to get the second half.

This result should be put in relation with propositions 4 and 10 and with the Poissonian Fock space structure defined above.

**Exercise 26.** Show that using theorem 2, corollary 4 implies that for any function \( F \) of an non-negative field and any edge \((x_i, y_i)\): \( \mathbb{E}_\phi \left( \frac{1}{2} \left( \phi^x - \phi^y \right)^2 : F \left( \frac{1}{2} \phi^2 \right) \right) = \int \mathbb{E}(F(\hat{\mathcal{L}}^x_a) \tilde{T}^{(a)}_{x,y}) \)

\( \mathbb{E}_\phi \left( \phi^x \phi^y : F \left( \frac{1}{2} \phi^2 \right) \right) = -\int \mathbb{E}(F(\hat{\mathcal{L}}^x_a)N_{x,y}) \)

Hint: Express the Gaussian measure and use the fact that \( -\frac{\partial}{\partial \kappa_{x,y}} \log(\det(G)) = G^{x,x} + G^{y,y} - 2G^{x,y} \)

**Exercise 27.** Setting \( \tilde{t}^x = \tilde{\ell}^x - G^{x,x} \) and \( \tilde{T}_{x,y}(l) = T_{x,y}(l) - (G^{x,x} + G^{y,y} - 2G^{x,y}) \), show that we have:
\[
\int_{l} \mathcal{I}_x(l) \mu(dl) = (G^{x,y})^2 - G^{x,z} G^{y,z} = \det \begin{pmatrix} \langle \phi^x, \phi^x \rangle & \langle \phi^x, \phi^y \rangle \\ \langle \phi^y, \phi^x \rangle & \langle \phi^y, \phi^y \rangle \end{pmatrix}
\]

\[
\int_{l} \mathcal{T}_{y,z}(l) \mu(dl) = (G^{x,y} - G^{x,z})^2 - G^{x,z}(G^{z,y} + G^{y,y} - 2G^{y,z})
= \det \begin{pmatrix} \langle \phi^x, \phi^x \rangle & \langle \phi^x, \phi^y \rangle \\ \langle \phi^y, \phi^x \rangle & \langle \phi^y, \phi^y \rangle \end{pmatrix}
\]

\[
\int \mathcal{T}_{x,y}(l) \mathcal{T}_{u,v}(l) \mu(dl) = (G_{x,u} + G_{y,v} - G_{x,v} - G_{y,u})^2
- (G^{x,x} + G^{y,y} - 2G^{x,y})(G^{u,u} + G^{v,v} - 2G^{u,v})
= - \det \begin{pmatrix} \langle \phi^x - \phi^y, \phi^x \rangle & \langle \phi^x - \phi^y, \phi^y \rangle \\ \langle \phi^y, \phi^x \rangle & \langle \phi^y, \phi^y \rangle \end{pmatrix}.
\]

Exercise 28. For any bounded functional \( \Phi \) on loop configurations, give two different expressions for \( \frac{\partial^2}{\partial \kappa_x \partial \kappa_y} \mathbb{E}(\Phi(L_{\alpha})) \), \( \frac{\partial^2}{\partial C_{x,y} \partial \kappa_x} \mathbb{E}(\Phi(L_{\alpha})) \) and \( \frac{\partial^2}{\partial C_{x,y} \partial C_{u,v}} \mathbb{E}(\Phi(L_{\alpha})) \).

The proposition 21 is in fact the infinitesimal form of the following formula.

**Proposition 22.** Consider another energy form \( e' \) defined on the same graph. Then we have the following identity:

\[
\frac{\partial \mu_{e'}}{\partial \mu_e} = e \sum N_{x,y} \log \left( \frac{C'_{x,y}}{C_{x,y}} \right) - \sum (\lambda'_{e} - \lambda_{e})^\epsilon.
\]

Consequently

\[
\mu_e(e^{e' \sum N_{x,y} \log \left( \frac{C'_{x,y}}{C_{x,y}} \right) - \sum (\lambda'_{e} - \lambda_{e})^\epsilon} - 1)) = \log \left( \frac{Z_{e'}}{Z_e} \right). \tag{6.1}
\]

**Proof.** The first formula is a straightforward consequence of (2.6). The proof of (6.1) goes by evaluating separately the contribution of trivial loops, which equals \( \sum_{x} \log \left( \frac{\lambda'_{e}}{\lambda_{e}} \right) \). Indeed,

\[
\mu_e(e^{e' \sum N_{x,y} \log \left( \frac{C'_{x,y}}{C_{x,y}} \right) - \sum (\lambda'_{e} - \lambda_{e})^\epsilon} - 1)) = \mu_e(p > 1) - \mu_e(p > 1) + \mu_e(1 \{p = 1\} (e^{e' \sum (\lambda'_{e} - \lambda_{e})^\epsilon} - 1)).
\]

The difference of the first two terms equals \( \log(Z_{e'}) + \sum \log(\lambda'_{e}) - (\log(Z_e) - \sum \log(\lambda_{e})) \). The last term equals \( \sum_{x} \int_{0}^{\infty} \left( e^{\frac{\lambda'_{e} - \lambda_{e}}{t} - 1} \right) e^{-t} dt \) which can be computed as before:

\[
\mu_e(1 \{p = 1\} (e^{e' \sum (\lambda'_{e} - \lambda_{e})^\epsilon} - 1)) = - \sum \log \left( \frac{\lambda'_{e}}{\lambda_{e}} \right). \tag{6.2}
\]

Integrating out the holding times, formula (6.1) can be written equivalently:

\[
\mu_e\left( \prod_{(x,y)} \left( \frac{C'_{x,y}}{C_{x,y}} \right)^{N_{x,y}} \prod_{x} \left( \frac{\lambda'_{e}}{\lambda_{e}} \right)^{N_{x}+1} - 1 \right) = \log \left( \frac{Z_{e'}}{Z_e} \right). \tag{6.3}
\]

and therefore
Associated loop variable can be written

\[ \sum_{x} N_{x}(\mathcal{L}_{\omega}) x^{\lambda_{x}} N_{x}(\mathcal{L}_{\omega}) + 1 = \left( \frac{Z_{e'}}{Z_{e}} \right)^{\alpha} \]  

or equivalently

\[ \mathbb{E}(\prod_{(x,y)} \left( \frac{C'_{x,y}}{C_{x,y}} \right) N_{x,y}(\mathcal{L}_{\omega}) e^{-\lambda'} \mathcal{L}_{\omega} N_{x,y} + N_{y,x}) \]  

Note also that

\[ \prod_{(x,y)} \left( \frac{C'_{x,y}}{C_{x,y}} \right) N_{x,y} = \prod_{(x,y)} \left( \frac{C'_{x,y}}{C_{x,y}} \right) N_{x,y} + N_{y,x}. \]

**Remark 9.** These \( \frac{Z_{e'}}{Z_{e}} \) determine, when \( e' \) varies with \( \frac{C'}{C} \leq 1 \) and \( \frac{\lambda'}{\lambda} = 1 \), the Laplace transform of the distribution of the traversal numbers of non-oriented links \( N_{x,y} + N_{y,x} \).

**Remark 10.** (h-transforms) Note that if \( C'_{x,y} = h^{x} h^{y} C_{x,y} \) and \( \kappa'_{x} = -h^{x} (Lh)^{x} \lambda_{x} \) for some positive function \( h \) on \( E \) such that \( Lh \leq 0 \), as \( \lambda' = h^{2} \lambda \) and \( [P^{2}] = \frac{1}{h^{2}} P_{y} h^{y} \), we have \( [G^{2}] = \frac{h^{2}}{h^{2} h^{y}} \) and \( \frac{Z_{e'}}{Z_{e}} = \frac{1}{1(h^{2})^{2}}. \)

**Remark 11.** Note also that \( [\frac{Z_{e'}}{Z_{e}}]^{\frac{1}{2}} = \mathbb{E}_{\phi}(e^{-\frac{1}{2}(e'-e)(\phi)}) \), if \( \phi \) is the Gaussian free field associated with \( e \).

### 6.2 One-forms and representations

Other variables of interest on the loop space are associated with elements of the space \( \mathbb{A} \) of odd real valued functions \( \omega \) on oriented links: \( \omega^{x,y} = -\omega^{y,x} \).

Let us mention a few elementary results.

The operator \([P^{2}] = P_{y} \exp(\omega^{x,y})\) is also self-adjoint in \( L^{2}(\lambda) \). The associated loop variable can be written \( \sum_{x,y} \omega^{x,y} N_{x,y}(l) \). We will denote it \( \int_{l} \omega \). This notation will be used even when \( \omega \) is not odd. Note that \( \int_{l} \omega \) is invariant if \( \omega \) is replaced by \( \omega + dg \) for some \( g \). Set \( [G^{2}]x,y = \frac{(I - P^{x,y})^{-1})x}{\lambda_{y}}. \)

By an argument similar to the one given above for the occupation field, we have:

\[ \mathbb{E}_{x,y}(e^{i \int_{l} \omega} - 1) = \exp(t(P^{x,y} - I))^{x} - \exp(t(P - I))^{x}. \]

Integrating in \( t \) after expanding, we get from the definition of \( \mu \):

\[ \int (e^{i \int_{l} \omega} - 1) d\mu(l) = \sum_{k=1}^{\infty} \frac{1}{k} \left[ Tr((P^{x,y})^{k}) - Tr((P)^{k}) \right]. \]

Hence \( \int (e^{i \int_{l} \omega} - 1) d\mu(l) = \log(\det(-L(I - P^{x,y})^{-1})) = \log(\det(G^{x,y} G^{-1})) \).
We can now extend the previous formulas (6.3) and (6.4) to obtain, setting \( \det(G^{(\omega)}) = Z_{e,\omega} \)

\[
\int (e^{\sum N_{x,y} \log(x_{x,y}^\prime) - \sum (\lambda_x' - \lambda_x) i_{x,y} + \omega - 1) \mu_e(dl) = \log(Z_{e,\omega}') \tag{6.6}
\]

and

\[
E(\prod_{x,y} C_{x,y}' e^{i_{x,y} \omega})^{N_{x,y}'} e^{-\sum (\lambda_x' - \lambda_x) E_{x,y}^{(\gamma)}} = (Z_{e,\omega}')^\alpha \tag{6.7}
\]

Remark 12. The \( \alpha \)-th power of a complex number is a priori not univocally defined as a complex number. But \( \log(\det(I - P(\omega))) \) and therefore \( \log(Z_{e,\omega}) \) are well defined as \( P(\omega) \) is a contraction. Then \( Z_{e,\omega}^\alpha \) is taken to be \( \exp(\alpha \log(Z_{e,\omega})) \).

Remark 13. Note also that if \( \varphi = \phi_1 + i \phi_2 \) is the complex Gaussian free field associated with \( e \), and if we set \( e^{\gamma(\omega)}(\varphi) = \frac{1}{2} \sum (\lambda_x' - \lambda_x) \varphi^2 + \sum C_{x,y}' e^{i_{x,y} \omega} \varphi^2 \),

\[
\frac{Z_{e,\omega}'}{Z_e} = E(\varphi^{-\frac{1}{2}[\gamma(\omega) - \gamma(\varphi)])
\]

To simplify the notations slightly, one could consider more general energy forms with complex valued conductances so that the discrete one form is included in \( e' \). But it is more interesting to generalize the notion of perturbation of \( P \) into \( P^{(\omega)} \) as follows:

**Definition 1.** A unitary representation of the graph \((X, E)\) is a family of unitary matrices \([U^x.y]\), with common rank \( d_U \), indexed by \( E^G \), such that \([U^y.x] = [U^x.y]^{-1}\).

We set \( P(U) = \mathcal{P} \otimes U \) (more explicitly \([P(U)]_{x,i}^j = \mathcal{P}_{x} [U^y.x]_{i}^j\)).

Similarly, we can define \( C(U) = \frac{d}{d\lambda} P(U) \), \( V(U) = (I - P(U))^{-1} \), \( G(U) = \frac{dU}{\lambda} \). One should think of these matrices as square matrices indexed by \( X \), whose entries are multiples of elements of \( SU(d_U) \).

One forms define one-dimensional representations. The sum and tensor product of two unitary representations \( U \) and \( V \) are unitary representations are defined as usual, and their ranks are respectively \( d_U + d_V \) and \( d_U d_V \).

**Definition 2.** Given any based loop \( l \), if \( p(l) \geq 2 \) and the associated discrete based loop is \( \xi = (\xi_1, \xi_2, ..., \xi_p) \), set \( \tau_U(l) = \frac{1}{d_U} \text{Tr}(\prod U_{\xi_i, \xi_{i+1}}) \), and \( \tau_U(l) = 1 \) if \( p(l) = 1 \).

For any set of loops \( L \), we set \( \tau_U(L) = \prod_{l \in L} \tau_U(l) \).

Remark 14. a) \( |\tau_U(l)| \leq 1 \).

b) \( \tau_U \) is obviously a functional of the discrete loop \( \xi^o \) contained in \( l^o \).
c) \( \tau_U(l) = 1 \) if \( \xi^* \) is tree-like. In particular it is always the case when the graph is a tree.

d) If \( U \) and \( V \) are two unitary representations of the graph, \( \tau_{U+V} = \tau_U + \tau_V \) and \( \tau_{U \otimes V} = \tau_U \tau_V \).

From b) and c) above it is easy to get the first part of

Theorem 3. i) The trace \( \tau_U(l) \) depends only on the canonical geodesic loop associated with the loop \( \xi^* \), i.e. of the conjugacy class of the element of the fundamental group defined by the based loop \( \xi \).

ii) The variables \( \tau_U(l) \) determine, as \( U \) varies, the geodesic loop associated with \( l \).

Proof. The second assertion follows from the fact that traces of unitary representations separate the conjugacy classes of finite groups (Cf [44]) and from the so-called CS-property satisfied by free groups (Cf [53]): given two elements belonging to different conjugacy classes, there exists a finite quotient of the group in which they are not conjugate.

Let us fix a base point \( x_0 \) in \( X \) and a spanning tree \( T \). An oriented edge \((x, y)\) which is not in \( T \) defines an element \( \gamma_{x,y} \) of the fundamental group \( \Gamma_{x_0} \), with \( \gamma_{y,x} = \gamma_{x,y}^{-1} \). For any discrete based loop \( l = (x_1, x_2, ..., x_p) \), set \( \gamma_l = \gamma_{x_1,x_2}...\gamma_{x_{p-1},x_p} \gamma_{x_p,x_1} \). Then, if two based loops \( l_1 \) and \( l_2 \) define distinct geodesic loops, there exists a finite quotient \( G = \Gamma_{x_0}/H \) of \( \Gamma_{x_0} \) in which the classes of their representatives \( \gamma_l \) are not conjugate. Denote by \( \tau \) the class of \( \gamma \) in \( G \). Then there exists a unitary representation \( \rho \) of \( G \) such that \( Tr(\rho(\gamma_{l_1})) \neq Tr(\rho(\gamma_{l_2})) \). Then take \( U_{x,y} = \rho(\gamma_{x,y}) \). We see that \( \tau_U(l_1) \neq \tau_U(l_2) \).

Again, by an argument similar to the one given for the occupation field, we have:

\[
P^t_{x,x}(\tau_U - 1) = \frac{1}{d_U} \sum_{i=1}^{d_U} \exp(t(P^{(U)} - I))_{x,x}^i - \exp(t(P - I))_{x,x}^i.
\]

Integrating in \( t \) after expanding, we get from the definition of \( \mu \):

\[
\int (\tau_U(l) - 1) d\mu(l) = \sum_{k=1}^{\infty} \frac{1}{k} \left[ T r((P^{(U)})^k) - T r((P)^k) \right].
\]

We can extend \( P \) into a matrix \( P^{(I_{d_U})} = P \otimes I_{d_U} \) indexed by \( X \times \{1, ..., d_U\} \) by taking its tensor product with the identity on \( \mathbb{R}^{d_U} \).

Then:
\[
\int (\tau_U(l) - 1) d\mu(l) = \frac{1}{dU} \sum_{k=1}^{\infty} \frac{1}{k} \left[ \text{Tr}((P^{(U)})^k) - \text{Tr}((P^{(I_{dU}))}^k) \right].
\]

Hence, as in the case of the occupation field
\[
\int (\tau_U(l) - 1) d\mu(l) = \frac{1}{dU} \log(\det(V(U))[V \otimes I_{dU}]^{-1}) = \frac{1}{dU} \log(\det(G^{(U)})) - \log(\det(G))
\]
as \det(G \otimes I_{dU}) = \det(G)^{dU}.

Then, denoting \( Z_{e,U} \) the \( \left( \frac{1}{\pi_U} \right) \)-th power of the determinant of the \( (|X| dU, |X| dU) \) matrix \( G^{(U)} \) (well defined by remark 12), the formulas (6.6) and (6.7) extend easily to give the following

**Proposition 23.**

a) \( \int (e^{\sum N_{x,y}(l) \log(C_{x,y}^e)} - \sum (\lambda_x' - \lambda_x) \tau_U(l) - 1) \mu_e(dl) = \log\left( \frac{Z_{e,U}}{Z_{e}} \right) \).

b) \( E(\prod_{x,y} [C_{x,y}^e]^{N_{x,y}(\mathcal{L}_e)} e^{-\sum (\lambda_x' - \lambda_x) \mathcal{Z}_c} \tau_U(\mathcal{L}_e)) = \left( \frac{Z_{e,U}}{Z_{e}} \right)^\alpha \).

Let us now introduce a new

**Definition 3.** We say that sets \( A_1 \) of non-trivial loops are equivalent when the associated occupation fields are equal and when the total traversal numbers \( \sum_{l \in A_1} N_{x,y}(l) \) are equal for all oriented edges \( (x, y) \). Equivalence classes will be called loop networks on the graph. We denote \( \overline{A} \) the loop network defined by \( A \).

Similarly, a set \( L \) of non-trivial discrete loops defines a discrete network characterized by the total traversal numbers.

The expectations computed in 6.7 determine the distribution of the network \( \overline{\mathcal{L}_e} \) defined by the loop ensemble \( \mathcal{L}_e \). We will denote \( B^{e,e',\omega}(l) \) the variables
\[
e^{\sum N_{x,y}(l) \log(C_{x,y}^e)} - \sum (\lambda_x' - \lambda_x) \tau_l + \lambda_f \omega
\]
and \( B^{e,e',\omega}(\mathcal{L}_e) \) the variables
\[
\prod_{l \in \mathcal{L}_e} B^{e,e',\omega}(l) = \prod_{x,y} [C_{x,y}^{e,e'} e^{i \omega x,y}]^{N_{x,y}(\mathcal{L}_e)} e^{-\sum (\lambda_x' - \lambda_x) \mathcal{Z}_c}.
\]

More generally, we can define \( B^{e,e',U}(l) \) and \( B^{e,e',U}(\mathcal{L}_e) \) in a similar way as \( B^{e,e',\omega}(l) \) and \( B^{e,e',\omega}(\mathcal{L}_e) \), using \( \tau_U(l) \) instead of \( e^{i \omega l} \). Note that for each fixed \( e \), when \( U \) and \( e' \) vary with \( \frac{e'}{C} \leq 1 \) and \( \lambda' = \lambda \), linear combinations of the variables \( B^{e,e',U}(\mathcal{L}_e) \) form an algebra as \( B^{e,e',U_1} B^{e',e',U_2} = B^{e,e',U_1 \otimes U_2} \), with \( C^{e',2} = \frac{C_e e'}{e' C} \). In particular, \( B^{e,e',1} B^{e,e',2} = B^{e,e',1+2} \).

**Remark 15.** Note that the expectations of the variables \( B^{e,e',\omega}(\mathcal{L}_e) \) determine the law of the network \( \overline{\mathcal{L}_e} \) defined by the loop ensemble \( \mathcal{L}_e \).
To work with $\mu$, we should rather consider linear combinations of the form 
$$\sum \lambda_i (B^{e,e_i,U_i} - 1),$$
with $\sum \lambda_i = 0$, which form also an algebra.

**Remark 16.** Formulas (6.6) and (6.7) apply to the calculation of loop indices: If we have for example a simple random walk on an oriented planar graph, and if $z'$ is a point of the dual graph $X'$, $\omega(z')$ can be chosen such that for any loop $l$, $\int_l \omega(z')$ is the winding number of the loop around a given point $z'$ of the dual graph $X'$. Then $e^{i\pi \sum_{l \in L} \int_l \omega(z')}$ is a spin system of interest. We then get for example that

$$\mu\left( \int_l \omega(z') \neq 0 \right) = -\frac{1}{2\pi} \int_0^{2\pi} \log(\det(2\pi u \omega(z'))) \, du$$

and hence

$$P\left( \sum_{l \in L} |\int_l \omega(z')| = 0 \right) = e^{2\pi \int_0^{2\pi} \log(\det(2\pi u \omega(z'))) \, du}.$$ 

Conditional distributions of the occupation field with respect to values of the winding number can also be obtained.
Chapter 7
Decompositions

Note first that with the energy $e$, we can associate a time-rescaled Markov chain $\hat{x}_t$ in which holding times at any point $x$ are exponential times of parameters $\lambda_x$: $\hat{x}_t = x_{\tau_t}$ with $\tau_t = \inf(s, \int_0^s \frac{1}{\lambda_u} du = t)$. For the time-rescaled Markov chain, local times coincide with the time spent in a point and the duality measure is simply the counting measure. The potential operator then essentially coincides with the Green function. The Markov loops can be time-rescaled as well and we did it in fact already when we introduced pointed loops. More generally we may introduce different holding time parameters but it would be rather useless as the random variables we are interested in are intrinsic, i.e. depend only on $e$.

7.1 Traces of Markov chains and energy decomposition

If $D \subset X$ and we set $F = D^c$, the orthogonal decomposition of the energy $e(f, f) = e(f)$ into $e^D(f - HF f)$ (see proposition 17) leads to the decomposition of the Gaussian free field mentioned above and also to a decomposition of the time-rescaled Markov chain into the time-rescaled Markov chain killed at the exit of $D$ and its trace on $F$, i.e. $\hat{x}_t^{(F)} = \hat{x}_{S_t^F}$, with $S_t^F = \inf(s, \int_0^s 1_F(\hat{x}_u) du = t)$.

**Proposition 24.** The trace of the time-rescaled Markov chain on $F$ is the time-rescaled Markov chain defined by the energy functional $e^{(F)}(f) = e(H^F f)$, for which

\[
C^{(F)}_{x,y} = C_{x,y} + \sum_{a,b \in D} C_{x,a} C_{b,y} [G^D]_{a,b}^{a,b},
\]

\[
\lambda_x^{(F)} = \lambda_x - \sum_{a,b \in D} C_{x,a} C_{b,x} [G^D]_{a,b}^{a,b},
\]

and
\[ Z_x = Z_x^F. \]

**Proof.** For the second assertion, note first that for any \( y \in F \),
\[
[H^F]^x_y = 1_{x=y} + 1_D(x) \sum_{b \in D} [G^D]^x_b C_{b,y}.
\]

Moreover, \( e(H^F) = e(f, H^F) \), by proposition 17 and therefore
\[
\lambda^x_F = e(F)(1_{\{x\}}) = e(1_{\{x\}}, H^F 1_{\{x\}}) = 1 - \sum_{a \in D} C_{x,a} [H^F]^x_a = \lambda_x (1 - p^F_x)
\]
where \( p^x_F = \sum_{a,b \in D} P^x_a [G^D]^a_b C_{b,x} = \sum_{a \in D} P^x_a [H^F]^a_x \) is the probability that the Markov chain starting at \( x \) will first perform an excursion in \( D \) and then return to \( x \).

Then for distinct \( x \) and \( y \) in \( F \),
\[
C^x_{x,y} = -e(F)(1_{\{x\}}, 1_{\{y\}}) = -e(1_{\{x\}}, H^F 1_{\{y\}}) = C_{x,y} + \sum_a C_{x,a} [H^F]^a_y = C_{x,y} + \sum_{a,b \in D} C_{x,a} C_{b,y} [G^D]^a_b.
\]

Note that the graph defined on \( F \) by the non-vanishing conductances \( C^F_{x,y} \) has in general more edges than the restriction to \( F \) of the original graph.

For the third assertion, note also that \( G^F \) is the restriction of \( G \) to \( F \) as for all \( x, y \in F \), \( e(F)(G \delta_{y} F, 1_{\{x\}}) = e(G \delta_{y}, [H^F 1_{\{x\}}]) = 1_{x=y} \). Hence the determinant decomposition already given in section 4.3 yields the formula.

The cases where \( F \) has one point was considered as a special case in 4.3.

For the first assertion note the transition matrix \( P^F_x \) can be computed directly and equals
\[
P^x_y = \sum_{a, b \in D} P^x_a [V^D \cup \{x\}]^a_b P^b_y = \sum_{a, b \in D} P^x_a [G^D \cup \{x\}]^a_b C_{b,y}.
\]

It can be decomposed according to whether the jump to \( y \) occurs from \( x \) or from \( D \) and the number of excursions from \( x \) to \( x \):
\[
[P^F_x]^x_y = \sum_{k=0}^{\infty} \left( \sum_{a,b \in D} P^x_a [V^D]^a_b P^b_y \right) k \left( \sum_{a,b \in D} P^x_a [V^D]^a_b P^b_y \right)
= \sum_{k=0}^{\infty} \left( \sum_{a,b \in D} P^x_a [G^D]^a_b C_{b,x} \right) k \left( \sum_{a,b \in D} P^x_a [G^D]^a_b C_{b,y} \right).
\]

The expansion of \( \frac{C^F_{x,y}}{\lambda^x_F} \) in geometric series yields exactly the same result.

Finally, remark that the holding times of \( \hat{\tau}_t^F \) at any point \( x \in F \) are sums of a random number of independent holding times of \( \hat{\tau}_x \). This random integer counts the excursions from \( x \) to \( x \) performed by the chain \( \hat{\tau}_x \) during
the holding time of $\hat{z}_i^{(F)}$. It follows a geometric distribution of parameter $1 - p_x^{(F)}$. Therefore, 
\[
\frac{1}{\lambda_x^{(F)}} = \frac{1}{\lambda_x(1-p_x^{(F)})}
\]
is the expectation of the holding times of $\hat{z}_i^{(F)}$ at $x$.

7.2 Excursion theory

A loop in $X$ which hits $F$ can be decomposed into a loop in $F$ and its excursions in $D$ which may come back to their starting point.

More precisely, a loop $l$ hitting $F$ can be decomposed into its restriction $l^{(F)} = (\xi_i, \hat{\tau}_i)$ in $F$ (possibly a one point loop), a family of excursions $\gamma_{\xi_i, \xi_{i+1}}$ attached to the jumps of $l^{(F)}$ and systems of i.i.d. excursions $(\gamma_{i, h}^h, h \leq \xi_i)$ attached to the points of $l^{(F)}$. These sets of excursions can be empty.

Let $\mu_{D}^{a,b}$ denote the bridge measure (with mass $[G^{D}]^{a,b}$) associated with $e^D$.

Set
\[
\nu_{x,y}^D = \frac{1}{C_{x,y}}[C_{x,y}g_0 + \sum_{a,b\in D} C_{x,a}C_{b,x}^a \mu_{D}^{a,b}], \quad \nu_{x}^D = \frac{1}{\lambda_x p_x^{(F)}} \sum_{a,b\in D} C_{x,a}C_{b,x}^a \mu_{D}^{a,b})
\]
and note that $\nu_{x,y}^D(1) = \nu_{x}^D(1) = 1$.

Let $\mu^D$ be the restriction of $\mu$ to loops in contained in $D$. It is the loop measure associated to the process killed at the exit of $D$. We get a decomposition of $\mu - \mu^D$ in terms of the loop measure $\mu^{(F)}$ defined on loops of $F$ by the trace of the Markov chain on $F$, probability measures $\nu_{x,y}^D$ on excursions in $D$ indexed by pairs of points in $F$ and $\nu_{x}^D$ on excursions in $D$ indexed by points of $F$. Moreover, conditionally on $l^{(F)}$, the integers $\lambda_{\xi_i}$ follow a Poisson distribution of parameter $(\lambda_{\xi_i} - \lambda_{\xi_i}^{(F)})\hat{\tau}_i$ (the total holding time in $\xi_i$ before another point of $F$ is visited) and the conditional distribution of the rescaled holding times in $\xi_i$ before each excursion $\gamma_{\xi_i}^l$ is the distribution $\beta_{\lambda_{\xi_i}, \hat{\tau}_i}$ of the increments of a uniform sample of $\lambda_{\xi_i}$ points in $[0, \hat{\tau}_i]$ put in increasing order. We denote these holding times by $\hat{\tau}_{i,h}$ and set
\[
l = \Lambda(l^{(F)}, (\gamma_{\xi_i, \xi_{i+1}}), (\lambda_{\xi_i}, \gamma_{\xi_i}^h, \hat{\tau}_{i,h})).
\]

Then $\mu - \mu^D$ is the image measure by $\Lambda$ of
\[
\mu^{(F)}(dl^{(F)}) \prod_{i} \nu_{\xi_i, \xi_{i+1}}^D(d\gamma_{\xi_i, \xi_{i+1}}) e^{-(\lambda_{\xi_i} - \lambda_{\xi_i}^{(F)})\hat{\tau}_i} \sum_k \frac{[(\lambda_{\xi_i} - \lambda_{\xi_i}^{(F)})\hat{\tau}_i]^k}{k!} \delta_{\lambda_{\xi_i}, \hat{\tau}_i} \nu_{x}^D \otimes k(d\gamma_{\xi_i}^h) \beta_{h, \hat{\tau}_i} (d\hat{\tau}_{i,h}).
\]

Note that for $x, y$ belonging to $F$, the bridge measure $\mu_{x,y}^D$ can be decomposed in the same way, with the same excursion measures.
The one point case and the excursion measure

If \( F \) is reduced to a point \( x_0 \), and \( \kappa \) vanishes on \( D = \{ x_0 \}^c \), the decomposition is of course simpler.

First, \( \lambda_{x_0} = \sum_a C_{x_0,a} + \kappa_{x_0} \) and \( \lambda_{x_0}^{(x_0)} = \kappa_{x_0} \). Then,

\[
p_{x_0}^{(x_0)} = \sum_{a,b \in D} P_{x_0}^a [G^D]_{a,b} C_{b,x_0} = \sum_{a} C_{x_0,a} \lambda_{x_0} = 1 - \frac{\kappa_{x_0}}{\lambda_{x_0}}
\]
as \( C_{.,x_0} \) is the killing measure of \( e^D \) and therefore its \( G^D \) potential equals 1.

\( t^{(x_0)} \) is a trivial one point loop with rescaled lifetime \( \hat{\tau} = \tilde{\tau}_{x_0} \frac{\lambda_{x_0}}{\kappa_{x_0}} = \frac{\tilde{\tau}_{x_0}}{1 - \mu_{x_0}^{(x_0)}} \)

and the number of excursions (all independent with the same distribution \( \rho_{x_0}^{(x_0)} \)) follows a Poisson distribution of parameter \( \kappa_{x_0} \hat{\tau} = \lambda_{x_0} \hat{\tau}_{x_0} \).

The non-normalized excursion measure

\[
\rho^D = (\lambda_{x_0} - \kappa_{x_0}) \mu_{x_0}^D = \sum_{a,b \in D} C_{x_0,a} C_{b,x_0} \mu_{D}^{a,b}
\]

verifies the following property: for any subset \( K \) of \( D \),

\[
\rho^D(\{ \gamma, \tilde{\gamma}(K) > 0 \}) = \text{Cap}_{e,D}(K).
\]

Indeed, the left-hand side can be expressed as

\[
\sum_{a,b \in D} C_{x_0,a} C_{b,x_0} [H^K G^D]_{a,b} = \sum_{a \in D} C_{x_0,a} [H^K 1]^a = e^D (1, H^K 1).
\]

It should be noted that \( \rho^D \) depends only of \( e^D \) (i.e. does not depend on \( \kappa_{x_0} \)).

**Proposition 25.**

a) Under \( \rho^D \), the non-normalized hitting distribution of any \( K \subseteq D \) is the \( e^D \)-capacitary measure of \( K \). The same property holds for the last hitting distribution.

b) Under \( \rho^D(\cdot \gamma) \), the conditional distribution of the path \( \gamma \) between \( T_K (\gamma) \) (the first time in \( K \)) and \( L_K (\gamma) \) (the last time in \( K \)), given \( \gamma_{T_K} \) and \( \gamma_{L_K} \) is \( \mu_{K} \). The same property holds for the last hitting distribution.

**Proof.**

a) By definition of \( \rho^D \), the non-normalized hitting distribution of \( K \) is expressed for any \( z \in K \) by \( \sum_{a,b,c \in D} C_{x_0,a} C_{b,x_0} [G^{D-K}]_{a,c} C_{c,z} [G^D]_{z,b} = \sum_{a,c \in D} C_{x_0,a} [G^{D-K}]_{a,c} C_{c,z} \), \( C_{x_0,a}, a \in D \) is the killing measure of \( e^D \)

b) Indeed, on functions of a path after \( T_K \),

\[
\mu_{D}^{a,b} = \sum_{a,c \in D, z \in K} C_{x_0,a} [G^{D-K}]_{a,c} C_{c,z} \mu_{D}^{z,b}
\]

and therefore on functions of a path restricted to \( [T_K, L_K] \), \( \rho^D \) equals:
\[ \sum_{z \in K} \sum_{a,b,c \in D} C_{x_0,a}[G^{D-K}]^{a,c}C_{c,z}G^{d,b}C_{b,x_0} \]
\[ = \sum_{z,t \in K} \sum_{a,b,c,d \in D} C_{x_0,a}[G^{D-K}]^{a,c}C_{c,z}G^{d,b}C_{b,x_0} \]

Remark 17. This construction of \( \rho^D \) can be extended to transient chains on infinite spaces with zero killing measure. There exists a unique measure on equivalence classes under the shift of doubly infinite paths converging to infinity on both sides, such that the hitting distribution of any compact set is given by its capacitary measure (Cf [14], [58], [48], and the first section of [55] for a recent presentation in the case of \( \mathbb{Z}^d \) random walks). Proposition 25 holds also in this context.

Following [55], the set of points hit by a Poissonian set of excursions of intensity \( \alpha \rho^D \) can be called the interlacement at level \( \alpha \).

The law \( \mu_{x_0}^{G_{x_0},x_0} \) can of course be decomposed in the same way, with the same conditional distribution given \( \tilde{x}_0 \). Recall that by proposition 9, \( \tilde{x}_0 \) follows an exponential distribution with mean \( G_{x_0,x_0} \).

\( \tilde{x}_0 \) follows a \( \Gamma(\alpha, G_{x_0,x_0}) \) distribution, in particular an exponential distribution with mean \( G_{x_0,x_0} \) for \( \alpha = 1 \). Moreover, the union of the excursions of all loops of \( L \) outside \( x_0 \) has obviously the same Poissonian conditional distribution, given \( \tilde{x}_0 = s \) than \( \mu \) and \( \mu_{x_0}^{G_{x_0},x_0} \), given \( \tilde{x}_0 = s \). The set of excursions outside \( x_0 \) defined by the \( \mu_{x_0}^{G_{x_0},x_0} \)-distributed bridge and by \( L \) are therefore identically distributed, as the total holding time in \( x_0 \).

Remark 18. Note finally that by exercise 13, the distribution of \( L_1/L^D \) can be recovered from a unique sample of \( \tilde{x}_0 \) by splitting the bridge according to an independent sample \( U \) of Poisson – Dirichlet(0, \( \alpha \)), more precisely, by splitting the bridge (in fact a based loop) \( l \) into based subloops \( l|_{[\sigma_i, \sigma_{i+1}]} \), with \( \sigma_i = \inf(s, \frac{1}{\lambda} \int_0^s 1_{(x_0)}(l_s)ds = \sum_{l \in L_1} U_j \tilde{l}_0) \).

Conversely, a sample of the bridge could be recovered from a sample of the loop set \( L_1/L^D \) by concatenation in random order. This random ordering can be defined by taking a projective limit of the randomly ordered finite subset of loops \( \{l_{i,n}\} \) defined by assuming for example that \( \tilde{l}_{i,n} > \frac{1}{n} \).

7.3 Conditional expectations

Coming back to the general case, the Poisson process \( L_1^{(F)} = \{l^{(F)}, l \in L_1\} \) has intensity \( \mu^{(F)} \) and is independent of \( L_1^{(D)} \).

Note that \( L_1^{(F)} \) is the restriction of \( \tilde{L}_1 \) to \( F \).
If $\chi$ is carried by $D$ and if we set $e_\chi = e + \|L^2(\chi)\|$ and denote $[e_\chi]^F$ by $e^{\{F,\chi\}}$ we have

$$C_{x,y}^{\{F,\chi\}} = C_{x,y} + \sum_{a,b} C_{x,a} C_{b,y} (G^D)^{a,b}, \quad p_x^{\{F,\chi\}} = \sum_{a,b \in D} P_{a} \big[ (G^D)^{a,b} \big] C_{b,x}$$

and $\lambda^{\{F,\chi\}} = \lambda_x (1 - p_x^{\{F,\chi\}})$.

More generally, if $e^#$ is such that $C^# = C$ on $F \times F$, and $\lambda = \lambda^#$ on $F$ we have:

$$C_{x,y}^{\{F\}} = C_{x,y} + \sum_{a,b} C_{x,a}^{\{F\}} C_{b,y}^{\{F\}} (G^D)^{a,b}, \quad p_x^{\{F\}} = \sum_{a,b \in D} P_{a} \big[ (G^D)^{a,b} \big] C_{b,x}^{\{F\}}$$

and $\lambda^{\{F\}} = \lambda_x (1 - p_x^{\{F\}})$.

If $\chi$ is a measure carried by $D$, we have:

$$\mathbb{E}(e^{-\langle \hat{\mathcal{L}}_\alpha, \chi \rangle} | \mathcal{L}^{\{F\}}_\alpha) = \mathbb{E}(e^{-\langle \hat{\mathcal{L}}^D_\alpha, \chi \rangle} \prod_{x,y \in F} \left[ \int e^{-\langle \hat{\mathcal{L}}^{D}_\alpha, \gamma \rangle} \nu_{x,y}^D (d\gamma) \right]^{N_{x,y}(\mathcal{L}^{\{F\}}_\alpha)} \times \prod_{x \in F} e^{(\lambda_x - \lambda^{\{F\}}_x) | \mathcal{L}^{\{F\}}_\alpha |} f(e^{-\langle \hat{\mathcal{L}}^{D}_\alpha, \chi \rangle} - 1) e^D (d\gamma)$$

$$= \frac{Z_{c,D}}{Z_{c,D}}^{\alpha} \left( \prod_{x,y \in F} \frac{C_{x,y}^{\{F,\chi\}}}{C_{x,y}^{\{F\}}} \right)^{N_{x,y}(\mathcal{L}^{\{F\}}_\alpha)} \prod_{x \in F} e^{-\lambda^{\{F\}}_x + \lambda^{\{F\}}_x} \hat{\mathcal{L}}^{D}_\alpha \mathcal{L}^{\{F\}}_\alpha$$

(recall that $\mathcal{L}^{\{F\}}_\alpha$ is the restriction of $\mathcal{L}_\alpha$ to $F$). Also, if we condition on the set of discrete loops $D \mathcal{L}^{\{F\}}_\alpha$

$$\mathbb{E}(e^{-\langle \hat{\mathcal{L}}_\alpha, \chi \rangle} | D \mathcal{L}^{\{F\}}_\alpha) = \frac{Z_{c,D}}{Z_{c,D}}^{\alpha} \left( \prod_{x,y \in F} \frac{C_{x,y}^{\{F,\chi\}}}{C_{x,y}^{\{F\}}} \right)^{N_{x,y}(\mathcal{L}^{\{F\}}_\alpha)} \prod_{x \in F} \left[ \frac{\lambda^{\{F\}}_x}{\lambda^{\{F\}}_x} \right]^{N_{x}(\mathcal{L}^{\{F\}}_\alpha) \alpha}$$

where the last exponent $N_x + 1$ is obtained by taking into account the loops which have a trivial trace on $F$ (see formula (6.2)).

More generally we can show in the same way the following

**Proposition 26.** If $C^# = C$ on $F \times F$, and $\lambda = \lambda^#$ on $F$, we denote $B^{e,c^#}$ the multiplicative functional

$$\prod_{x,y} \frac{C_{x,y}^{\{F\}}}{C_{x,y}^{\{F\}}} e^{-\sum_{x \in E} \hat{\mathcal{L}} (\lambda^{\{F\}}_x - \lambda_x)}.$$

Then,

$$\mathbb{E}(B^{e,c^#} | \mathcal{L}^{\{F\}}_\alpha) = \frac{Z_{c,D}}{Z_{c,D}}^{\alpha} \left( \prod_{x,y \in F} \frac{C_{x,y}^{\{F\}}}{C_{x,y}^{\{F\}}} \right)^{N_{x,y}(\mathcal{L}^{\{F\}}_\alpha)} \prod_{x \in F} \left[ \frac{\lambda^{\{F\}}_x}{\lambda^{\{F\}}_x} \right]^{N_{x}(\mathcal{L}^{\{F\}}_\alpha) \alpha}$$

and
\[
\mathbb{E}(B^{e,#} | D \mathcal{L}_{\alpha}^{(F)}) = \frac{Z_{e,#}^{D}}{Z_{e,#}^{D}} ( \prod_{x,y \in F} \left[ \frac{C_{x,y}^{(F)}}{C_{x,y}^{(F)}} \right]^{N_{x,y}(\mathcal{L}_{\alpha}^{(F)})} \prod_{x \in F} \left[ \frac{\lambda_{x}^{(F)}}{\lambda_{x}^{(F)}} \right]^{N_{x}(\mathcal{L}_{\alpha}^{(F)})} )^{+}.\]

These decomposition and conditional expectation formulas extend to include a current \( \omega \) in \( C^{#} \). Note that if \( \omega \) is closed (i.e. vanish on every loop) in \( D \), one can define \( \omega^{F} \) such that \( C_{x}^{\lambda \omega^{F}}(F) = C_{x}^{\lambda \omega}(F) \). Then
\[
Z_{e,\omega} = Z_{e,#}^{D} Z_{e,(F),\omega^{F}}.\]

The previous proposition implies the following Markov property:

**Remark 19.** If \( D = D_{1} \cup D_{2} \) with \( D_{1} \) and \( D_{2} \) strongly disconnected, (i.e. such that for any \( (x,y,z) \in D_{1} \times D_{2} \times F \), \( C_{x,y} \) and \( C_{x,z} C_{y,z} \) vanish), the restrictions of the network \( \overline{L}_{\alpha} \) to \( D_{1} \cup F \) and \( D_{2} \cup F \) are independent conditionally on the restriction of \( L_{\alpha} \) to \( F \).

**Proof.** This follows from the fact that as \( D_{1} \) and \( D_{2} \) are strongly disconnected, any excursion measure \( \nu^{D}_{x,y} \) or \( \rho^{D}_{x} \) from \( F \) into \( D = D_{1} \cup D_{2} \) is an excursion measure either in \( D_{1} \) or in \( D_{2} \).

### 7.4 Branching processes with immigration

An interesting example can be given after extending slightly the scope of the theory to countable transient symmetric Markov chains: We can take \( X = \mathbb{N} - \{0\} \), \( C_{n,n+1} = 1 \) for all \( n \geq 1 \), \( \kappa_{n} = 0 \) for \( n \geq 2 \) and \( \kappa_{1} = 1 \). \( P \) is the transfer matrix of the simple symmetric random walk killed at 0.

Then we can apply the previous considerations to check that \( \hat{L}_{\alpha}^{n} \) is a branching process with immigration.

The immigration at level \( n \) comes from the loops whose infimum is \( n \) and the branching from the excursions to level \( n + 1 \) of the loops existing at level \( n \). Set \( F_{n} = \{1, 2, ..., n\} \) and \( D_{n} = F_{n}^{c} \).

From the calculations of conditional expectations made above, we get that for any positive parameter \( \gamma \),
\[
\mathbb{E}(e^{-\gamma \hat{L}_{\alpha}^{n} || \mathcal{L}^{(F_{n-1})}_{\alpha}}) = \mathbb{E}(e^{-\gamma \hat{L}_{\alpha}^{n}})^{n} e^{(\hat{L}_{\alpha}^{n-1, \gamma} \mathcal{L}^{n-1}_{\alpha} - \hat{L}_{\alpha}^{n-1} \mathcal{L}^{n-1}_{\alpha})^{n}}
\]
(\( \hat{L}_{\alpha}^{n-1} \) denotes the occupation field of the trace of \( L_{\alpha} \) on \( D_{n-1} \) evaluated at \( n \)).

From this formula, it is clear that \( \hat{L}_{\alpha}^{n} \) is a branching Markov chain with immigration. To be more precise, note that for any \( n, m > 0 \), the potential operator \( V_{m}^{n} \) equals \( 2(n \wedge m) \) that \( \lambda_{n} = 2 \) and that \( G^{1,1} = 1 \). Moreover, by the
generalized resolvent equation, $G_{\gamma \delta_1}^{1,n} = G^{1,n} - G^{1,1} \gamma G_{\gamma \delta_1}^{1,n}$ so that $G_{\gamma \delta_1}^{1,n} = \frac{1}{1+\gamma}$.

For any $n > 0$, the restriction of the Markov chain to $D_n$ is isomorphic to the original Markov chain. Then it comes that for all $n$, $p_\alpha^{(F_n)} = \frac{1}{2}$, $\lambda_n^{(F_n)} = 1$, and $\lambda_n^{(F_n, \gamma \delta_{n+1})} = 2 - \frac{1}{1+\gamma} = \frac{2\gamma + 1}{1+\gamma}$ so that the Laplace exponent of the convolution semigroup $\nu_t$ defining the branching mechanism $\lambda^{(F_n-1, \gamma \delta_n)} - \lambda^{(F_n-1)}$ equals 
\[
2\gamma + 1 - 1 = \frac{\gamma}{1+\gamma} = \int (1 - e^{-\gamma s}) e^{-s} ds. \text{ It is the semigroup of a compound Poisson process whose Levy measure is exponential.}
\]

The immigration law (on $\mathbb{R}^+$) is a Gamma distribution $\Gamma(\alpha, G^{1,1}) = \Gamma(\alpha, 1)$. It is the law of $\hat{L}_1^{\alpha}$ and also of $[\hat{L}^{D_{n-1}}_\alpha]$ for all $n > 1$.

The conditional law of $\hat{L}_n^{\alpha+1}$ given $\hat{L}_n^{\alpha}$ is the convolution of the immigration law $\Gamma(\alpha, 1)$ with $\nu_\alpha^{\hat{L}_n}$.

**Exercise 29.** Alternatively, we can consider the integer valued process $N_n(\mathcal{L}_\alpha^{(F_n)}) + 1$ which is a Galton Watson process with immigration. In our example, we find the reproduction law $\pi(n) = 2^{-n-1}$ for all $n \geq 0$ (critical binary branching).

**Exercise 30.** Show that more generally, if $C_{n,n+1} = \frac{[\hat{L}^{D_n}]^n}{1-p}$, for $n > 0$ and $\kappa_1 = 1$, with $0 < p < 1$, we get all asymmetric simple random walks. Show that $\lambda_n = \frac{p^{n-1}}{1-p}$ and $G^{1,1} = 1$. Determine the distributions of the associated branching and Galton Watson process with immigration.

If we consider the occupation field defined by the loops whose infimum equals 1 (i.e. going through 1), we get a branching process without immigration: it is the classical relation between random walks local times and branching processes.

### 7.5 Another expression for loop hitting distributions

Let us come back to formula 4.9. Setting $F = F_1 \cup F_2$, we see that this result involves only $\mu^{(F)}$ and $e^{(F)}$ i.e. it can be expressed in terms of the restrictions of the loops to $F$.

**Lemma 1.** If $X = X_1 \cup X_2$ with $X_1 \cap X_2 = \emptyset$,
\[
\log(\frac{\det(G)}{\det(G^{X_1}) \det(G^{X_2})}) = \sum_{k=1}^{\infty} \frac{1}{2k} Tr([H_{12}H_{21}]^k + [H_{12}H_{21}]^k)
\]

with $H_{12} = H^{X_2}|_{X_1}$ and $H_{21} = H^{X_1}|_{X_2}$.

**Proof.**
Another expression for loop hitting distributions

\[
\frac{\det(G)}{\det(G^{X_1})\det(G^{X_2})} = \left( \frac{\det \left( \begin{array}{cc}
I_{X_1 \times X_1} & -G^{X_1}C_{X_1 \times X_2} \\
-G^{X_2}C_{X_2 \times X_1} & I_{X_2 \times X_2}
\end{array} \right)}{\det \left( \begin{array}{cc}
-I_{X_1 \times X_1} & -H_{12} \\
-H_{21} & I_{X_2 \times X_2}
\end{array} \right)} \right)^{-1}.
\]

The transience implies that either \( H_{12} \) or \( H_{21} \) is strictly less than 1, and therefore, \( H_{12}H_{21} \) and \( H_{12}H_{21}^{-1} \) are strict contractions. From the expansion of \(-\log(1-x)\), we get that:

\[
\log \left( \frac{\det(G)}{\det(G^{X_1})\det(G^{X_2})} \right) = \sum_{k=1}^{\infty} \frac{1}{k} \text{Tr} \left[ \begin{array}{cc}
0 & -H_{12} \\
-H_{21} & 0
\end{array} \right]^k.
\]

The result follows, as odd terms have obviously zero trace.

Noting finally that the lemma can be applied to the restrictions of \( G \) to \( F_1 \cup F_2, F_1 \) and \( F_2 \), and that hitting distributions of \( F_1 \) from \( F_2 \) and \( F_2 \) from \( F_1 \) are the same for the Markov chain on \( X \) and its restriction to \( F_1 \cup F_2 \), we get finally:

**Proposition 27.** If \( F_1 \) and \( F_2 \) are disjoint,

\[
\mu(\hat{l}(F_1)\hat{l}(F_2) > 0) = \sum_{k=1}^{\infty} \frac{1}{2k} \text{Tr}([H_{12}H_{21}]^k + [H_{21}H_{12}]^k)
\]

with \( H_{12} = H_{F_2|F_1} \) and \( H_{21} = H_{F_1|F_2} \).

**Exercise 31.** Show that the \( k \)-th term of the expansion can be interpreted as the measure of loops with exactly \( k \)-crossings between \( F_1 \) and \( F_2 \).

**Exercise 32.** Prove analogous results for \( n \) disjoint sets \( F_i \).
Chapter 8
Loop erasure and spanning trees.

8.1 Loop erasure

Recall that an oriented link \( g \) is a pair of points \((g^-, g^+)\) such that \( C_g = C_{g^-, g^+} \neq 0 \). Define \(-g = (g^+, g^-)\).

Let \( \mu_{x,y}^\neq \) be the measure induced by \( C \) on discrete self-avoiding paths between \( x \) and \( y \):

\[ \mu_{x,y}^\neq = \left( x, x_2, ..., x_{n-1}, y \right) = C_{x,x_2}C_{x_1,x_3}...C_{x_{n-1},y}. \]

Another way to define a measure on discrete self avoiding paths from \( x \) to \( y \) from a measure on paths from \( x \) to \( y \) is loop erasure defined in section 3.1 (see also \([18], [41], [19] \) and \([33]\)). In this context, the loops, which can be reduced to points, include holding times, and loop erasure produces a discrete path without holding times.

We have the following:

**Theorem 4.** The image of \( \mu_{x,y}^\neq \) by the loop erasure map \( \gamma \rightarrow \gamma^{BE} \) is \( \mu_{BE}^{x,y} \) defined on self avoiding paths by

\[ \mu_{BE}^{x,y}(\eta) = \mu_{x,y}^{\neq}(\eta) \frac{\det(G)}{\det(G(\eta)^\gamma)} = \mu_{x,y}^{\neq}(\eta) \det(G_{\gamma(\eta) \times \gamma(\eta)}) \]

(Here \( \{ \eta \} \) denotes the set of points in the path \( \eta \) and by \( \mu_{BE}^{x,y}() = \delta^x_y G_{x,x} \))

**Proof.** Set \( \eta = (x_1 = x, x_2, ..., x_n = y) \) and \( \eta_m = (x, ..., x_m) \), for any \( m > 1 \). Then,

\[ \mu_{x,y}^{\neq}(\gamma^{BE} = \eta) = \sum_{k=0}^{\infty} \left[ P^k \right]_{x}^{x_2} P^x_{x_2} \mu_{x_2,y}^{\theta \eta} \]

where \( \mu_{x,y}^{\neq} \) denotes the bridge measure for the Markov chain killed as it hits \( x \) and \( \theta \) the natural shift on discrete paths. By recurrence, this clearly equals

\[ V_x P^x_{x_2} [V(x)^\gamma x_2]_{x_2} [V(\eta_{n-1})]_{x_{n-1}} P^y_{\eta_{n-1}} [V(\eta_{n-1})^\gamma y]_{y} = \mu_{x,y}^{\neq}(\eta) \frac{\det(G)}{\det(G(\eta)^\gamma)} \]

as
8 Loop erasure and spanning trees.

\[ \det([I - P]^{\gamma_m}) = \frac{\det(V^{\eta_m - 1}_x)}{\det(V^{\eta_1}_x)} = \frac{\det(G^{\eta_1}_x)}{\det(G^{\eta_m}_x)} \lambda_x \]

for all \( m \leq n - 1 \).

**Remark 20.** It is worth noticing that, also the operation of loop erasure clearly depends on the orientation of the path (as shown in the picture below), the distribution of the loop erased bridge is reversible.

![Orientation dependence](image)

Also, by Feynman-Kac formula, for any self-avoiding path \( \gamma \):

\[
\int e^{-\langle \gamma,\lambda' \rangle} 1_{\{\gamma^{BE}=\eta\}} \mu^{x,y} (d\gamma) = \frac{\det(G_\chi)}{\det(G^{\eta}_\chi)} \mu^{x,y} (\eta) = \frac{\det(G_\chi)}{\det(G^{\eta}_\chi)} \mu^{x,y} (\eta).
\]

Therefore, recalling that by the results of section 4.3 conditionally on \( \eta \), \( \mathcal{L} / \mathcal{L}_1^{(\eta)} \) and \( \mathcal{L}_1^{(\eta)} \) are independent, we see that under \( \mu^{x,y} \), the conditional distribution of \( \widehat{\gamma} \) given \( \gamma^{BE} = \eta \) is the distribution of \( \widehat{L}_1 - \widehat{L}_1^{[\eta]} \) i.e. the occupation field of the loops of \( \mathcal{L}_1 \) which intersect \( \eta \).

More generally, it can be shown that

**Proposition 28.** The conditional distribution of the network \( \overline{\mathcal{L}}_{\gamma} \) defined by the loops of \( \gamma \), given that \( \gamma^{BE} = \eta \), is identical to the distribution of \( \overline{\mathcal{L}}_{\gamma} \) defined by \( \mathcal{L}_1 / \mathcal{L}_1^{(\eta)} \) i.e. the loops of \( \mathcal{L}_1 \) which intersect \( \eta \).

**Proof.** Recall the notation \( Z_\varepsilon = \det(G) \). First an elementary calculation using (2.8) shows that \( \mu^{x,y} (e^{\int_{\gamma^{BE=\eta}} \omega} 1_{\gamma^{BE=\eta}}) \) equals

\[
\frac{C_{\varepsilon}^{x,y}}{C_{\varepsilon}^{x,y}} \frac{C_{\varepsilon}^{x_1,x_2} \cdots C_{\varepsilon}^{x_{n-1},y}}{C_{\varepsilon}^{x_1,x_2} \cdots C_{\varepsilon}^{x_{n-1},y}} \int_{\gamma^{BE=\eta}} \overline{\mathcal{L}}_{\gamma} \mu^{x,y} \left( \prod_{u \neq v} \frac{C_{u,v}^{1,\omega \varepsilon}}{C_{u,v}} \right) e^{-\langle \gamma^{BE=\eta} \rangle}.
\]
(Note the term $e^{-\langle \lambda', \gamma \rangle}$ can be replaced by $\prod_{\omega} (\frac{2\pi}{N_0})^{N_\omega (\gamma + 1)}$).

Moreover, by the proof of the previous proposition, applied to the Markov chain defined by $e'$ perturbed by $\omega$, we have also

$$\mu^{x,y}_{e'}(e^{i\gamma} \mathbf{1}_{\{\gamma_{BE} = \eta\}}) = C_{x,x_2} C_{x_1,x_3} \ldots C_{x_{n-1},y} e^{i\int_{\eta}^{e'} \omega} \frac{Z_{e',\omega}}{Z_{[e']^{\gamma}}^{e',\omega}}.$$}

Therefore,

$$\mu^{x,y}_{e}(\prod_{u \neq v} \frac{C_{u,v}}{E_{u,v}} e^{i\omega_{u,v}} N_{u,v}(E_v) e^{-\langle \lambda', \gamma \rangle} |_{\gamma_{BE} = \eta}) = \frac{Z_{e}(\eta)^v Z_{e',\omega}}{Z_e Z_{[e']^{\gamma}}^{e',\omega}}.$$}

Moreover, by (6.7) and the properties of the Poisson processes,

$$\mathbb{E}(\prod_{u \neq v} \frac{C_{u,v}}{E_{u,v}} e^{i\omega_{u,v}} N_{u,v}(E_v) e^{-\langle \lambda', \gamma \rangle} |_{\gamma_{BE} = \eta}) = \frac{Z_{e}(\eta)^v Z_{e',\omega}}{Z_e Z_{[e']^{\gamma}}^{e',\omega}}.$$}

It follows that the joint distribution of the traversal numbers and the occupation field are identical for the set of erased loops and $L_1/L_1^{\gamma}$.

The general study of loop erasure which is done in this chapter yields the following result when applied to a universal covering $\tilde{\mathbb{X}}$. Let $\tilde{G}$ be the Green function associated with the lift of the Markov chain.

**Corollary 5.** The image of $\mu^{x,y}$ under the reduction map is given as follows:

If $c$ is a geodesic arc between $x$ and $y$: $\mu^{x,y}(\{\xi, \xi^R = c\}) = \prod_{c \in \xi \cup \xi^R} \det(G_{\{c\} \times \{c\}}).$

Besides, if $\tilde{x}$ and $\tilde{y}$ are the endpoints of the lift of $c$ to a universal covering,

$$\mu^{x,y}(\{\xi, \xi^R = c\}) = \tilde{G}_{\tilde{x}, \tilde{y}}.$$}

Note this yields an interesting identity on the Green function $\tilde{G}$.

**Exercise 33.** Check it in the special case treated in proposition 13.

Similarly one can define the image of $P^x$ by $BE$ and check it is given by

$$P^x_{BE}(\eta) = \delta_{x_1} C_{x_1,x_2} \cdots C_{x_{n-1},x_n} \kappa_{x_n} \det(G_{\{\eta\} - \Delta \times \{\eta\} - \Delta})$$

$$= \delta_{x_1} C_{x_1,x_2} \cdots C_{x_{n-1},x_n} \kappa_{x_n} \frac{\det(G)}{\det(G_{\{\eta\} - \Delta \times \{\eta\} - \Delta})}$$

for $\eta = (x_1, \ldots, x_n, \Delta)$.

Note that in particular, $P^x_{BE}(\{x, \Delta\}) = V^x_x (1 - \sum_y P^x_y) = \kappa_x G^{x,x}.$

Slightly more generally, one can determine the law of the image, by loop erasure path killed at it hits a subset $F$, the hitting point being now the end point of the loop erased path (instead of $\Delta$, unless $F$ is not hit during the lifetime of the path). If $x \in D = F^c$ is the starting point and $y \in F^D$, the probability of $\eta = (x_1, \ldots, x_n, y)$ is
84 8 Loop erasure and spanning trees.

\[\delta(x_1, x_2, \ldots, x_{n-1}, x_n, y) \det(G_D^{[\eta]}_{\eta \times \eta}) = \delta(x_1, x_2, \ldots, x_{n-1}, x_n, y) \frac{\det(G_D)}{\det(G_D^{[\eta]}_{\eta \times \eta})}\]

8.2 Wilson algorithm

Wilson’s algorithm (see [31]) iterates this last construction, starting with the points \(x\) arranged in an arbitrary order. The first step of the algorithm is the construction of a loop erased path starting at the first point and ending at \(\Delta\). This loop erased path is the first branch of the spanning tree. Each step of the algorithm reproduces this first step except it starts at the first point which is not visited by the already constructed tree of self avoiding paths, and stops when it hits that tree, or \(\Delta\), producing a new branch of the tree. This algorithm provides a construction, branch by branch, of a random spanning tree rooted in \(\Delta\). It turns out, as we will show below, that the distribution of this spanning tree is very simple, and does not depend on the ordering chosen on \(X\).

More precisely, we start at \(x_0\) a Markov chain path \(\omega_1\), then if \(n_1\) denotes \(\inf(i, x_i \notin \omega_1^{BE})\), we start at \(x_{n_1}\) a Markov chain path \(\omega_2\) killed as it hits \(\omega_1^{BE}\) or \(\Delta\), etc...until the space is covered by the branches \(\omega_j^{BE}\), which form a spanning tree \(\tau(\omega)\) rooted in \(\Delta\).

Given \(\Upsilon\) a spanning tree rooted in \(\Delta\), denote by \(\eta_1\) the geodesic in \(\Upsilon\) between \(x_0\) and \(\Delta\), then by \(\eta_2\) the geodesic between \(x_{\inf\{j, x_j \notin \eta_1\}}\) and \(\{\eta_2 \cup \Delta\}\) etc...Then:

\[P(\tau = \Upsilon) = P(\omega_1^{BE} = \eta_1)P(\omega_2^{BE} = \eta_2 | \omega_1^{BE} = \eta_1)\ldots\]

This law is a probability measure \(P_{ST}^e\) on the set \(ST_{X, \Delta}\) of spanning trees of \(X\) rooted at the cemetery point \(\Delta\) defined by the energy \(e\). The weight attached to each oriented link \(g = (x, y)\) of \(X \times X\) is the conductance and the weight attached to the link \((x, \Delta)\) is \(\kappa_x\) which we can also denote by \(C_{x, \Delta}\).

As the determinants simplify in the iteration, the probability of a tree \(\Upsilon\) is given by a simple formula:

\[P_{ST}^e(\Upsilon) = Z_e \prod_{\xi \in \Upsilon} C_{\xi}\] (8.1)

It is clearly independent of the ordering chosen initially. Now note that, since we get a probability

\[Z_e \sum_{\Upsilon \in ST_{X, \Delta}} \prod_{(x, y) \in \Upsilon} C_{x, y} \prod_{x \in (x, \Delta) \in \Upsilon} \kappa_x = 1\] (8.2)

or equivalently
Fig. 8.2 Wilson algorithm

\[
\sum_{\tau \in ST, \Delta} \prod_{(x,y) \in \tau} p^x_y \prod_{x, (x, \Delta) \in \tau} p^x_{\Delta} = \prod_{x \in X} \frac{1}{\lambda_x Z_e} 
\]

Then, it follows that, for any \( e' \) for which conductances (including \( \kappa' \)) are positive only on links of \( e \),

\[
E_{ST}^e \left( \prod_{(x,y) \in \tau} \frac{P^x_y}{p^x_y} \prod_{x, (x, \Delta) \in \tau} \frac{P^x_{\Delta}}{p^x_{\Delta}} \right) = \frac{\prod_{x \in X} \lambda_x Z_e}{\prod_{x \in X} \lambda'_x Z_{e'}} 
\]

and

\[
E_{ST}^{e'} \left( \prod_{(x,y) \in \tau} \frac{C_{x,y}'}{C_{x,y}} \prod_{x, (x, \Delta) \in \tau} \frac{\kappa'_x}{\kappa_x} \right) = \frac{Z_{e'}}{Z_{e}}. \quad (8.3)
\]

Note also that in the case of a graph (i.e. when all conductances are equal to 1), all spanning trees have the same probability. The expression of their cardinal as the determinant \( Z_e \) is known as Cayley’s theorem (see for example [31]).

The formula (8.3) shows a kind of duality between random spanning trees and \( \mathcal{L}_1 \). It can be extended to \( \mathcal{L}_k \) for any integer \( k \) if we consider the sum (in terms of number of transitions) of \( k \) independent spanning trees.

The symmetry is not crucial in this argument. In fact, it shows as well that for any submarkovian transition matrix \( P' \),

\[
\det(I - P') = \sum_{\tau \in ST, \Delta} \prod_{(x,y) \in \tau} [P']^x_y \prod_{x, (x, \Delta) \in \tau} (1 - \sum_y [P']^y_g) 
\]
It follows that for any matrix $L'$, with $[L']^x_y \leq 0$ for all $x \neq y$ and $[L']^x_x - \sum_y [L']^x_y \geq 0$ for all $x$, we have:

$$\det(L') = \sum_{\Upsilon \in \text{ST}_X, \Delta} \prod_{(x,y) \in \Upsilon} [L']^x_y \prod_{x,(x,\Delta) \in \Upsilon} ([L']^x_x - \sum_y [L']^y_x)$$

The result extends to any complex matrix $L'$ by the principle of isolated zeros.

In particular, given any 1-form $\omega^{x,y}$, it follows that:

$$\sum_{\Upsilon \in \text{ST}_X, \Delta} \left( \prod_{(x,y) \in \Upsilon} C_{x,y} e^{i\omega^{x,y}} \prod_{x,(x,\Delta) \in \Upsilon} \kappa_x - \sum_y C_{x,y}(e^{i\omega^{x,y}} - 1) \right) = \det(M \lambda - Ce^{i\omega})$$

or equivalently

$$\mathbb{E}_{\text{ST}}\left( \prod_{(x,y) \in \Upsilon} e^{i\omega^{x,y}} \prod_{x,(x,\Delta) \in \Upsilon} (1 - \frac{1}{\kappa_x}(\sum_y C_{x,y}(e^{i\omega^{x,y}} - 1)) \right) = \frac{Z_e}{Z_{e,\omega}}.$$

More generally

$$\mathbb{E}_{\text{ST}}\left( \prod_{(x,y) \in \Upsilon} \frac{C'_{x,y}}{C_{x,y}} e^{i\omega^{x,y}} \prod_{x,(x,\Delta) \in \Upsilon} \frac{1}{\kappa_x}(\kappa'_x - (\sum_y C'_{x,y}(e^{i\omega^{x,y}} - 1)) \right) = \frac{Z_e}{Z'_{e,\omega}}.$$

**Exercise 34.** Show that more generally, for any tree $T$ rooted in $\Delta$,

$$P_{\text{ST}}(\{T, T \subseteq \Upsilon\}) = \det(G_{\{T\} \times \Delta \setminus \{T\} \times \Delta} \prod_{\xi \in \text{Edges}(\Delta)} C_{\xi}, \{T\}$$

denoting the vertex set of $T$.

(As usual, $C_{x,\Delta} = \kappa_x$. Hint: Run Wilson’s algorithm starting from the leaves of $T$)

**Exercise 35.** Using exercise 3, prove Cayley’s Theorem: the complete graph $K_n$ has $n^{n-2}$ spanning trees.

The following result follows easily from proposition 28.

**Corollary 6.** The network defined by the random set of loops $L_W$ constructed in this algorithm is independent of the random spanning tree, and independent of the ordering. It has the same distribution as the network defined by the loops of $L_1$.

**Remark 21.** Note that proposition 28 and its corollary can be made more precise with the help of remark 18. The splitting procedure used there with the help of an auxiliary independent set of Poisson Dirichlet variables allows to reconstruct the set of loops $L_1/L_1^{y,y}$ by splitting the first erased loop in the proof of the proposition. Iterating the procedure we can successively
reconstruct all sets $L^{(\eta_m)} / L^{(\eta_{m+1})}$ and finally $L / L^{(\eta)}$. Then, by Wilson algorithm, we can reconstruct $L_1$.

Let us now consider the recurrent case.

A probability is defined on the non oriented spanning trees by the conductances: $P_{ST}(T)$ is defined by the product of the conductances of the edges of $T$ normalized by the sum of these products on all spanning trees.

Note that any non oriented spanning tree of $X$ along edges of $E$ defines uniquely an oriented spanning tree $I_\Delta(T)$ if we choose a root $\Delta$. The orientation is taken towards the root which can be viewed as a cemetery point. Then, if we consider the associated Markov chain killed as it hits $\Delta$ defined by the energy form $\epsilon^{(\Delta)}$, the previous construction yields a probability $P_{ST}^{(\Delta)}$ on spanning trees rooted at $\Delta$ which by (8.1) coincides with the image of $P_{ST}$ by $I_\Delta$. This implies in particular that the normalizing factor $Z_{\epsilon^{(\Delta)}}$ is independent of the choice of $\Delta$ as it has to be equal to $(\sum_{T \in ST_X} \prod_{\{x,y\} \in T} C_{x,y})^{-1}$.

We denote it by $Z_{\epsilon}^0$. This factor can also be expressed in terms of the recurrent Green operator $G$. Recall it is defined as a scalar product on measures of zero mass. The determinant of $G$ is defined as the determinant of its matrix in any orthonormal basis of this hyperplane, with respect to the natural euclidean scalar product.

Recall that for any $x \neq \Delta$, $G(\epsilon_x - \epsilon_\Delta) = -\frac{\langle \lambda, G^{(\Delta)} \epsilon_x \rangle}{\lambda(\chi)} + G^{(\Delta)} \epsilon_x$. Therefore, for any $y \neq \Delta$, $\langle \epsilon_y - \epsilon_\Delta, G(\epsilon_x - \epsilon_\Delta) \rangle = |G^{(\Delta)}|_{x,y}$.

The determinant of the matrix $[G^{(\Delta)}]_{x,y}$, equal to $Z_{\epsilon}^0$, is therefore also the determinant of $G$ in the basis $\{\delta_x - \delta_\Delta, x \neq \Delta\}$ which is not orthonormal with respect to the natural euclidean scalar product. An easy calculation shows it equals

$$\det \left( \langle \delta_y - \delta_\Delta, \delta_x - \delta_\Delta \rangle_{\mathbb{R}^{\chi_1}}, x, y \neq \Delta \right) \det(G) = |X| \det(G).$$

Exercise 36. Prove that if we set $\alpha_{x_0}(T) = \prod_{\{x,y\} \in I_{x_0}(T)} P_{y}^{\epsilon_x} \sum_{T \in ST_X} \alpha_{x_0}(T)$ is proportional to $\lambda x_0$ as $x_0$ varies in $X$. More precisely, it equals $K \lambda x_0$, with $K = \frac{Z_{\epsilon}^0}{\prod_{x \in X} x_x}$. This fact is known as the matrix-tree theorem ([31]).

Exercise 37. Check directly that $Z_{\epsilon^{(x_0)}}$ is independent of the choice of $x_0$.

Exercise 38. Given a spanning tree $T$, we say a subset $A$ is wired iff the restriction of $T$ to $A$ is a tree.

a) Let $\bar{\epsilon}_A$ be the recurrent energy form defined on $A$ by the conductances $C$. Show that $P_{ST}(A$ is wired$) = \frac{Z_{\epsilon}^{0}}{Z_{\epsilon^{(\bar{\epsilon}_A)}}^{0} - Z_{\epsilon^{(\bar{\epsilon}_A)}}^{0}}$ (Hint: Choose a root in $A$. Then use exercise 34 and identity 8.2).
b) Show that under $P_{ST}^A$, given that $A$ is wired, the restriction of the spanning tree of $X$ to $A$ and the spanning tree of $A^c \cup \{\Delta\}$ obtained by rooting at an external point $\Delta$ the spanning forest induced on $A^c$ by restriction of the spanning tree are independent, with distributions respectively given by $P_{ST}^A$ and $P_{ST}^{A^c}$.

c) Conversely, given such a pair, the spanning tree of $X$ can be recovered by attaching to $A$ the roots $y_i$ of the spanning forest of $A^c$ independently, according to the distributions $C_{y_i,u}$, $u \in A$.

8.3 The transfer current theorem

Let us come back to the transient case by choosing some root $x_0 = \Delta$. As by the strong Markov property, $V_x^y = P_x(T_x < \infty)V_x^x$, we have $G_{x,y} = V_x^y = V_x^x$, and therefore

$P_{ST}^e((x, y) \in T) = P_x(\gamma_{BE} = y) = V_x^x P_y^x P_T^y(T_x = \infty) = C_{x,y} G^{x,x}(1 - G^{x,y}) G^{x,x}$.

Directly from the above, we recover Kirchhoff’s theorem:

$P_{ST}^e(\pm(x, y) \in T) = C_{x,y} [G^{x,x}(1 - G^{x,y}) + G^{y,y}(1 - G^{y,x})]$

$= C_{x,y} (G^{x,x} + G^{y,y} - 2G^{x,y}) = C_{x,y} K(x,y)(x,y)$

with the notation introduced in section 1.5, and this is clearly independent of the choice of the root.

Exercise 39. Give an alternative proof of Kirchhoff’s theorem by using (8.3), taking $C'_{x,y} = sC_{x,y}$ and $C'_{u,v} = C_{u,v}$ for $\{u, v\} \neq \{x, y\}$.

In order to go further, it is helpful to introduce some elements of exterior algebra. Recall that in any vector space $E$, in terms of the ordinary tensor product $\otimes$, the skew symmetric tensor product $v_1 \wedge v_2 \wedge ... \wedge v_n$ of $n$ vectors $v_1...v_n$ is defined as $\frac{1}{\sqrt{n!}} \sum_{\sigma \in S_n} (-1)^{m(\sigma)} v_{\sigma(1)} \otimes ... \otimes v_{\sigma(n)}$. They generate the $n$-th skew symmetric tensor power of $E$, denoted $E^\wedge n$. Obviously, $v_{\sigma(1)} \wedge ... \wedge v_{\sigma(n)} = (-1)^{m(\sigma)} v_1 \wedge v_2 \wedge ... \wedge v_n$. If the vector space is equipped with a scalar product $\langle.,.\rangle$, it extends to tensors and $\langle v_1 \wedge v_2 \wedge ... \wedge v_n, v'_1 \wedge v'_2 \wedge ... \wedge v'_n \rangle = \det(\langle v_i, v'_j \rangle)$.

The following result, which generalizes Kirchhoff’s theorem, is known as the transfer current theorem (see for example [30], [31]):

Theorem 5. $P_{ST}^e(\pm \xi_1, ..., \pm \xi_k \in T) = (\prod_{i=1}^k C_{\xi_i}) \det(K^{\xi_i,\xi_j} 1 \leq i, j \leq k)$. 

Note this determinant does not depend on the orientation of the links.

**Proof.** Note first that if \( T \) is a spanning tree rooted in \( x_0 = \Delta \) and \( \xi_i = (x_{i-1}, x_i), 1 \leq i \leq |X| - 1 \) are its oriented edges, the measures \( \delta_{x_i} - \delta_{x_{i-1}} \) form another basis of the euclidean hyperplane of signed measures with zero charge, which has the same determinant as the basis \( \delta_{x_i} - \delta_{x_0} \).

Therefore, \( Z_e^0 \) is also the determinant of the matrix of \( G \) in this basis, i.e.

\[
Z_e^0 = \det(K_{\xi_i \xi_j}, 1 \leq i, j \leq |X| - 1)
\]

and

\[
\mathbb{P}^e_{ST}(T) = (\prod_{1}^{X-1} C_{\xi_i}) \det(K_{\xi_i \xi_j}, 1 \leq i, j \leq |X| - 1)
= \det(\sqrt{C_{\xi_i} K_{\xi_i \xi_j} \sqrt{C_{\xi_j}}}, 1 \leq i, j \leq |X| - 1).
\]

Recall that \( K_{\xi_i \xi_j} K_{\xi_j \xi_i} = \langle \alpha_{\xi_i}^* | \Pi | \alpha_{\xi_j}^* \rangle_{\wedge \Delta} \), where \( \Pi \) denotes the projection on the space of discrete differentials of functions ( contained in in \( \wedge \Delta \)) and that \( \alpha_{\xi_i \xi_j}^* \) is nonzero if \( (x, y) = \pm(\eta) \) and is zero elsewhere.

To finish the proof of the theorem, it is helpful to use the exterior algebra. Note first that for any ONB \( e_1, ..., e_{|X|-1} \) of the space of discrete differentials, \( \Pi \alpha_{\xi_i}^* = \sum \langle \alpha_{\xi_i}^* | e_j \rangle e_j \) and \( \mathbb{P}^e_{ST}(T) = \det(\langle \alpha_{\xi_i}^* | e_j \rangle)^2 = \langle \alpha_{\xi_i}^* \wedge ... \wedge \alpha_{\xi_{|X|-1}}^* | e_1 \wedge ... \wedge e_{|X|-1} \rangle_{\wedge \Delta} \). Therefore

\[
\mathbb{P}^e_{ST}(\xi_1, ..., \xi_k \in T)
= \sum_{\eta_{k+1}, ..., \eta_{|X|-1}} \langle \alpha_{\xi_1}^* \wedge ... \wedge \alpha_{\xi_k}^* \wedge \alpha_{\eta_{k+1}}^* \wedge ... \wedge \alpha_{\eta_{|X|-1}}^* | e_1 \wedge ... \wedge e_{|X|-1} \rangle_{\wedge \Delta}^2
\]

where the sum is on all edges \( \eta_{k+1}, ..., \eta_{|X|-1} \) completing \( \xi_1, ..., \xi_k \) into a spanning tree. It can be extended to all systems of distinct \( q = |X| - 1 - k \) edges \( \eta' = \{\eta'_1, ..., \eta'_q\} \) as all the additional term vanish. Indeed, an exterior product of \( \alpha_{\xi_i}^* \) vanishes as soon as they form a loop. Hence the expression above equals:

\[
\sum_{\eta'} (\sum_{i_1 < ... < i_k} \varepsilon_{i_1}...i_k \langle \alpha_{\xi_1}^* \wedge ... \wedge \alpha_{\xi_k}^* | e_{i_1} \wedge ... \wedge e_{i_k} \rangle \langle \alpha_{\eta'_1}^* \wedge ... \wedge \alpha_{\eta'_q}^* | e_{i_1} \wedge ... \wedge e_{i_k} \rangle)^2
\]

where the \( i_j' \) are the indices complementing \( i_1, ..., i_k \) put in increasing order and \( \varepsilon_{i_1...i_k} = (-1)^{(i_1-1)...(i_k+k)} \). Recalling that the \( \alpha_{\xi_i}^* \) form an orthonormal base of \( \wedge \Delta \), we see that the sum in \( \eta' \) of each mixed term in the square vanishes and
\[
\sum_{\eta} \langle \alpha_{\eta_1}^* \wedge ... \wedge \alpha_{\eta_k}^* | e_{i_1} \wedge ... \wedge e_{i_k} \rangle^2 = 1.
\]

Hence we obtain finally:
\[
\sum_{i_1 < ... < i_k} \langle \alpha_{\xi_1}^* \wedge ... \wedge \alpha_{\xi_k}^* | e_{i_1} \wedge ... \wedge e_{i_k} \rangle^2 \Lambda_{H_\omega} = \det(\sqrt{C_{\xi_i, \xi_j}} \sqrt{C_{\xi_i}} 1 \leq i, j \leq k).
\]

which ends the proof of the theorem.

It follows that given any function \( g \) on non oriented links,\[
\mathbb{E}_{ST}^e(e^{-\sum_{\xi \in T} g(\xi)}) = \mathbb{E}_{ST}^e(\prod_{\xi} (1 + (e^{-g(\xi)} - 1) \mathbb{P}_{ST}^e(\pm \xi_1, ..., \pm \xi_k \in T))
\]
\[
= 1 + \sum_{k=1}^{[E]} \sum_{\pm \xi_1 \neq \pm \xi_2 \neq ... \neq \pm \xi_k} \prod_{\xi} (e^{-g(\xi_i)} - 1) \mathbb{P}_{ST}^e(\pm \xi_1, ..., \pm \xi_k \in T)
\]
\[
= 1 + \sum_{k=1}^{[E]} \sum_{\pm \xi_1 \neq \pm \xi_2 \neq ... \neq \pm \xi_k} \prod_{\xi} (e^{-g(\xi_i)} - 1) \det(K_{\xi_i, \xi_j} 1 \leq i, j \leq k)
\]
\[
= 1 + \sum_{k} \text{Tr}((M_C(e^{-g(\xi_i)} - 1)^{\wedge k}) = \det(I + KM_C(e^{-g(\xi_i)} - 1))
\]

and we have proved the following

**Proposition 29.** \( \mathbb{E}_{ST}^e(e^{-\sum_{\xi \in T} g(\xi)}) = \det(I - M \sqrt{C(1-e^{-g})} KM \sqrt{C(1-e^{-g})}) \).

Here determinants are taken on matrices indexed by \( E \).

**Remark 22.** This is an example of the Fermi point processes (also called determinantal point processes) discussed in [51] and [47]. It is determined by the matrix \( M \sqrt{C} K M \sqrt{C} \). Note that it follows also easily from the previous proposition that the set of edges which do not belong to the spanning tree also form a Fermi point process defined by the matrix \( I - M \sqrt{C} K M \sqrt{C} \).

In particular, under \( \mathbb{P}_{ST}^e \), the set of points \( x \) such that \( (x, \Delta) \in T \) (i.e. the set of points directly connected to the root \( \Delta \)) is a Fermi point process the law of which is determined by the matrix \( Q^{x,y} = \sqrt{\kappa_x G^{x,y}} \sqrt{\kappa_y} \).

For example, if \( X \) is an interval of \( \mathbb{Z} \), with \( C_{x,y} = 0 \) iff \( |x - y| > 1 \), it is easily verified that for \( x < y < z \),
\[
Q^{x,z} = \frac{Q^{x,y} Q^{y,z}}{Q^{y,y}}
\]

Then using the remark following theorem 6 in [51], we see that the spacings of this point process are independent (in the sense that given any point of the process, the spacings on his right and on his left are independent).

The edges of \( X \) which do not belong to the spanning tree form a determinantal process of edges, of the same type, intertwined with the points connected to \( \Delta \).
8.3 The transfer current theorem

A consequence is that for any spanning tree $T$, if $\pi_T$ denotes $M_1(T)$ (the multiplication by the indicator function of $T$), it follows from the above, by letting $g$ be $m_1(T\cup \mathcal{T})$, $\pi \to \infty$ that

$$\mathbb{P}^e_{ST}(T) = \det((I - KM_C)(I - \pi_T) + \pi_T) = \det((I - K M_C)_{T\cup \mathcal{T}}).$$

Another consequence is that if $e'$ is another energy form on the same graph,

$$E^e_{ST}(\prod_{(x,y) \in T} \frac{C'_{x,y}}{C_{x,y}}) = \det(I - M_{\sqrt{C-C'}} K M_{\sqrt{C-C'}}).$$

On the other hand, from (8.3), it also equals

$$(\sum_{T \in ST} \prod_{(x,y) \in T} C_{x,y} Z^0_e) Z^0_e = Z^0_e Z^0_{e'} = \det(I - M_{\sqrt{C-C'}} K M_{\sqrt{C-C'}}).$$

Note that indicators of distinct individual edges are negatively correlated.

More generally:

**Theorem 6. (Negative association)** Given any sets disjoint of edges $E_1$ and $E_2$,

$$\mathbb{P}^e_{ST}(E_1 \cup E_2 \subseteq \mathcal{T}) \leq \mathbb{P}^e_{ST}(E_1 \subseteq \mathcal{T}) \mathbb{P}^e_{ST}(E_2 \subseteq \mathcal{T}).$$

**Proof.** Denote by $K^\#(i,j)$ the restriction of $K^\# = (\sqrt{C_k \xi, \eta}, \sqrt{C_{\xi, \eta}}, \xi, \eta \in E)$ to $E_i \times E_j$. Then,

$$\frac{\mathbb{P}^e_{ST}(E_1 \cup E_2 \subseteq \mathcal{T})}{\mathbb{P}^e_{ST}(E_1 \subseteq \mathcal{T}) \mathbb{P}^e_{ST}(E_2 \subseteq \mathcal{T})} = \frac{\det(K^\#)}{\det(K^\#(2,2)) \det(K^\#(2,2))} = \det\left(\left[ \begin{array}{cc} I & F^* \\ F & I \end{array} \right]\right)$$

with $F = K^\#(1,1)^{-\frac{1}{2}} K^\#(1,2) K^\#(2,2)^{-\frac{1}{2}}$.

Finally, note that $\log(\det(\left[ \begin{array}{cc} I & F^* \\ F & I \end{array} \right])) = \text{Tr}(\log(\left[ \begin{array}{cc} I & F^* \\ F & I \end{array} \right]))$

$$= -\sum_1^n \frac{1}{2k} \text{Tr}((FF^*)^k) \leq 0.$$

**Remark 23.** Note that it follows directly from the expression of $P_{ST}$ and from the transfer current theorem that for any set of disjoint edges $\xi_1, \ldots, \xi_k$:

$$[Z^0_e]^{-1} \frac{\partial^k}{\partial C_{\xi_1} \ldots \partial C_{\xi_k}} [Z^0_e]^{-1} = \det(K_{\xi_i, \xi_j}, 1 \leq i, j \leq k).$$

**Proof.** Note that
\[
\frac{\partial k}{\partial C_{\xi_1}... \partial C_{\xi_k}} [Z_e^0]^{-1} = \frac{\partial k}{\partial C_{\xi_1}... \partial C_{\xi_k}} \sum_{T \in ST_X} \prod_{\{x,y\} \in T} C_{x,y}^r \\
= [Z_e^0 \prod_{i=1}^k C_{\xi_i}]^{-1} e^{ST} (\pm \xi_1, ..., \pm \xi_k \in T).
\]

This result can be proved directly using for example Grassmann variables (as used in [25]). The transfer current theorem can then be derived immediately from it as shown in the following section.

### 8.4 The skew-symmetric Fock space

Consider the real Fermionic Fock space \( \Gamma^\wedge (\mathbb{H}^*) = \bigoplus \mathbb{H}^\wedge \otimes \mathbb{H} \) obtained as the closure of the sum of all skew-symmetric tensor powers of \( \mathbb{H}^* \) (the zero-th tensor power is \( \mathbb{R} \)). In terms of the ordinary tensor product \( \otimes \), the skew-symmetric tensor product \( \mu_1 \wedge ... \wedge \mu_n \) is defined as \( \frac{1}{\sqrt{n!}} \sum_{\sigma \in S_n} (-1)^m(\sigma) \mu_{\sigma(1)} \otimes \ldots \otimes \mu_{\sigma(n)} \). The construction of \( \Gamma^\wedge (\mathbb{H}^*) \) is known as Fermi second quantization.

For any \( x \in X \), the anihilation operator \( c_x \) and the creation operator \( c_x^* \) are defined as follows, on the uncompleted Fock space \( \bigoplus \mathbb{H}^\wedge \otimes \mathbb{H} \):

\[
c_x (\mu_1 \wedge ... \wedge \mu_n) = (-1)^{k-1} \sum_k G_{\mu_k}(x) \mu_1 \wedge ... \mu_{k-1} \wedge \mu_{k+1} \wedge ... \wedge \mu_n
\]

\[
c_x^* (\mu_1 \wedge ... \wedge \mu_n) = \delta_x \wedge \mu_1 \wedge ... \wedge \mu_n
\]

Note that \( c_y^* \) is the dual of \( c_y \) and that \( [c_x, c_y]^+ = G(x,y) \) with all others anticommutators vanishing.

We will work on the complex Fermionic Fock space \( \mathcal{F}_F \) defined the skew-symmetric tensor product of two copies of \( \Gamma^\wedge (\mathbb{H}^*) \) which is isomorphic to \( \Gamma^\wedge (\mathbb{H}_1^* + \mathbb{H}_2^*) \), \( \mathbb{H}_1 \) and \( \mathbb{H}_2 \) being two copies of \( \mathbb{H} \). The complex Fock space structure is defined by two anticommuting sets of creation and anihilation operators. \( \mathcal{F}_F \) is generated by the vector 1 and creation/anihilation operators \( c_x, c_x^*, d_x, d_x^* \) with \( [c_x, c_y]^+ = [d_x, d_y]^+ = G(x,y) \) and with all others anticommutators vanishing. Here, \( c_x^* \) creates \( \delta_x \) in \( \mathbb{H}_1^* \) and \( d_x^* \) creates \( \delta_x \) in \( \mathbb{H}_2^* \).

Anticommuting variables \( \psi^x, \overline{\psi}^x \) are defined as operators on the Fermionic Fock space \( \mathcal{F}_F \) by:

\[
\psi^x = \sqrt{2}(d_x + c_x^*) \quad \text{and} \quad \overline{\psi}^x = \sqrt{2}(-c_x + d_x^*).
\]

The following anticommutation relations hold

\[
[\psi^x, \psi^y]^+ = [\overline{\psi}^x, \psi^y]^+ = [\overline{\psi}^x, \overline{\psi}^y]^+ = 0
\]
In particular, \((\sum_x \lambda_x \psi^x)^2 = (\sum_x \lambda_x \overline{\psi}^x)^2 = 0\). Note that \(\overline{\psi}_x\) is not the dual of \(\psi_x\), but there is an involution \(\mathcal{I}\) on \(\mathcal{F}_F\) such that \(\overline{\psi} = \mathcal{I}\psi\mathcal{I}\).

\(\mathcal{I}\) is defined by its action on each tensor power: it multiplies each element in \(\mathbb{H}^{*,\wedge m} \otimes \mathbb{H}^{*,\wedge p}\) by \((-1)^m\).

**Exercise 40.** Show that in contrast with the Bosonic case, all these operators are bounded.

Simple calculations yield that:

\[
\langle 1, \psi^{x_1} \ldots \psi^{x_m} \overline{\psi}^{\overline{y}_1} \ldots \overline{\psi}^{\overline{y}_n} 1 \rangle = \delta_{mn} 2^n \det(G(x_i, y_j)).
\]

Therefore

\[
\langle 1, \psi^{x_n} \overline{\psi}^{\overline{y}_m} \ldots \psi^{x_1} \overline{\psi}^{\overline{y}_1} 1 \rangle = 2^n \det(G(x_i, y_j)).
\]

and

\[
\langle 1, \exp\left(-\frac{1}{2} e(\psi, \overline{\psi}) + \frac{1}{2} e'(\psi, \overline{\psi})\right) 1 \rangle_{\mathcal{F}_F} = \frac{\det(G)}{\det(G')}. \tag{1}
\]

Indeed, if \(f_i\) is an orthonormal basis of \(\mathbb{H}\), in which \(e'\) is diagonal with eigenvalues \(\lambda_i\), the first side equals

\[
\langle 1, \prod_i \exp\left(\frac{1}{2} (-1 + \lambda_i) \langle \psi, f_i \rangle \langle \overline{\psi}, f_i \rangle \right) 1 \rangle_{\mathcal{F}_F} = \langle 1, \prod_i (1 + \frac{1}{2} (-1 + \lambda_i) \langle \psi, f_i \rangle \langle \overline{\psi}, f_i \rangle \right) 1 \rangle_{\mathcal{F}_B} = 1 + \sum_{k} \sum_{i_1 < \ldots < i_k} (-1 + \lambda_{i_1}) \ldots (-1 + \lambda_{i_k}) = \prod \lambda_i.
\]

In particular, for any positive measure \(\chi\) on \(X\),

\[
\langle 1, \exp\left(\sum_x \chi_x \psi^x \overline{\psi}^x\right) 1 \rangle_{\mathcal{F}_F} = \frac{\det(G)}{\det(G_{\chi})} = \left(\langle 1, \exp\left(-\sum_x \chi_x \psi^x \overline{\psi}^x\right) 1 \rangle_{\mathcal{F}_B}\right)^{-1}.
\]

We observe a "Supersymmetry" between \(\phi\) and \(\psi\): for any exponential or polynomial \(F\)

\[
\langle 1, F(\overline{\phi} \overline{\psi} - \psi \overline{\psi}) 1 \rangle_{\mathcal{F}_B \otimes \mathcal{F}_F} = F(0).
\]

(1 denotes \(1_B \otimes 1_{\mathcal{F}}\))

**Remark 24.** On a finite graph, \(\psi_x, \overline{\psi}_x\) and the whole supersymmetric complex Fock space structure can also be defined in terms of complex differential forms defined on \(\mathcal{C}^1(X)\), using exterior products, interior products and De Rham * operator. This extension of the Gaussian representation of the complex Bosonic Fock space is explained in the introduction of [25]. It was used for example in [28].

Note that

\[
E_{ST}(\prod_{(x,y) \in \tau} \frac{C_{x,y}}{C_{x,y}} \prod_{x,(x,\delta) \in \tau} \frac{K_{x,\delta}}{K_{x}}) = \frac{Z_{e}}{Z_{e'}} = \left\langle 1, \exp\left(-\frac{1}{2} e(\psi, \overline{\psi}) + \frac{1}{2} e'(\psi, \overline{\psi})\right) 1 \right\rangle_{\mathcal{F}_F}.
\]
The Transfer Current Theorem follows directly, by calculation of
\[
P_{ST}((x_i, y_i) \in \tau) = \prod C_{x_i, y_i} \frac{\partial}{\partial C_{x_i, y_i}} |C' = C \langle 1, \exp\left(-\frac{1}{2} e(\psi, \bar{\psi}) + \frac{1}{2} e'(\psi, \bar{\psi})\right) \rangle_{\mathcal{F}_F} \\
= 2^{-k} \prod C_{x_i, y_i} \left(1, \left(\prod \left(\psi^{\bar{y}_i} - \psi^{\bar{x}_i}\right)\left(\bar{\psi}^{y_i} - \bar{\psi}^{x_i}\right)\right) \right)_{\mathcal{F}_F} \\
= \det(K(x_i, x_j)) \prod C_{x_i, y_i}.
\]

Note that in the second line we use the identity \(C_{x,y} = C_{y,x}\) to show that
\[
\frac{\partial}{\partial C'_{x,y}} e'(\psi, \bar{\psi}) = (\psi^{\bar{y}} - \psi^{\bar{x}})(\bar{\psi}^{y} - \bar{\psi}^{x}).
\]

In particular, \(P_{ST}((x_i, \delta) \in \tau) = \det(G(x_i, x_j)) \prod \kappa_x\).

More generally, we can show that
\[
\frac{Z_e}{Z_{e', \omega}} = E_{ST} \left( \prod_{(x,y)\in\tau} \frac{C'_{x,y}}{C_{x,y}} e^{i \omega_{x,y}} \prod_{x,(x,\delta)\in\tau} \frac{\kappa'_x - (\sum_y C'_{x,y}(e^{i \omega_{x,y}} - 1))}{\kappa_x} \right)
\]
and
\[
\frac{Z_e}{Z_{e', \omega}} = \left(1, \exp\left(\frac{1}{2} e(\psi, \bar{\psi}) - \frac{1}{2} e'(\omega)(\psi, \bar{\psi})\right) \right)_{\mathcal{F}_F}.
\]

Hence, if \((x_j, y_j)\) are disjoint, and \(T\) denotes the random spanning tree rooted in \(\Delta\), it follows that
\[
\prod \left(\frac{\partial}{\partial C'_{x_j, y_j}} - \frac{i}{C'_{x_j, y_j}} \frac{\partial}{\partial \omega_{x_j, y_j}} + \frac{\partial}{\partial \kappa'_{x_j}}\right) |C' = C, \omega = 0, \kappa' = -\frac{Z_e}{Z_{e', \omega}} = \frac{2}{C_{x_j, y_j}} P_{ST}((x_j, y_j) \in \tau).
\]

Therefore, we get the analogue of the transfer current theorem for rooted spanning trees:
\[
P_{ST}((x_j, y_j) \in \tau) = \prod 2^{-k} C_{x_j, y_j} \left(1, \left(\prod \psi^{\bar{y}_j} (\bar{\psi}^{y_j} - \bar{\psi}^{x_j})\right) \right)_{\mathcal{F}_F} \\
= \det(G^{x_j, y_k} - G^{x_j, x_k}) \prod C_{x_j, y_j}
\]

The relations we have established can be summarized in the following diagram:

```
(Wilson Algorithm)
Loop ensemble \(L_1\) ←→ Random Spanning Tree
↓ ↓
Free field \(\phi, \bar{\phi}\) ←→ Grassmann field \(\psi, \bar{\psi}\)
("Supersymmetry")
```
NB: $\phi$ and $\psi$ can also be used jointly to represent bridge functionals (Cf [25]): in particular

$$\int F(\hat{l})\mu_{x,y}(dl) = \langle 1, \phi_x \phi_y F(\phi \phi - \psi \psi) 1 \rangle_{\mathcal{F}_B \otimes \mathcal{F}_F} = \langle 1, \psi_x \psi_y F(\phi \phi - \psi \psi) 1 \rangle_{\mathcal{F}_B \otimes \mathcal{F}_F}.$$
Chapter 9
Reflection positivity

9.1 Main result

In this section, we assume there exists a partition of $X$: $X = X^+ \cup X^-$, $X^+ \cap X^- = \emptyset$ and an involution $\rho$ on $X$ such that:

a) $e$ is $\rho$-invariant.
b) $\rho$ exchanges $X^+$ and $X^-$.c) The $X^+ \times X^+$ matrix $C_{x,y}^\pm = C_{x,\rho(y)}$, is nonnegative definite.

Then the following holds:

Theorem 7. i) For any positive integer $d$ and square integrable function $\Phi$ in
\[
\sigma(\mathcal{L}_d^x, x \in X^+) \vee \sigma(N^{(d)}_{x,y}, x, y \in X^+),
\]
\[E(\Phi(L_d)(\rho(L_d))) \geq 0.\]

ii) For any square integrable function $\Sigma$ of the free field $\phi$ restricted to $X^+$,
\[E_\phi(\Sigma(\phi)\Sigma(\rho(\phi))) \geq 0.\]

iii) For any set of edges $\{\xi_i\}$ in $X^+ \times X^+$ the matrix,
\[K_{i,j} = P_{ST}^{\rho}(\xi_i \in T, \rho \xi_j \in T) - P_{ST}(\xi_i \in T)P_{ST}(\xi_j \in T)\]
is nonpositive definite.

Proof. The property ii) is well known in a slightly different context and is named reflection positivity: Cf for example [50], [13] and their references. Reflection positivity is a keystone in the bridge between statistical and quantum mechanics.

To prove i), we use the fact that the $\sigma$-algebra is generated by the algebra of random variables of the form $\Phi = \sum \lambda_j B_{(d)}^{x,\xi_j,\omega_j}$ with $C^{(\xi_j)} = C$ and $\omega_j = 0$.
except on $X^+ \times X^+$, $C(\epsilon) \leq C$ on $X^+ \times X^+$, $\lambda(\epsilon) = \lambda$ on $X^-$ and $\lambda(\epsilon) \geq \lambda$ on $X^+$.

Then

$$E(\Phi(L_d)\Psi(\rho(L_d))) = E(\sum \lambda_j \lambda_q B_{e,\epsilon_j \omega_j - \rho(\omega_q)} = \sum \lambda_j \lambda_q \frac{Z_{e_j \epsilon \omega \rho(\omega_q)}}{Z_e} d$$

with $e_j \omega = e_j + \rho(e_q) - e$.

We have to prove this is non negative. It is enough to prove it for $d = 1$, as the Hadamard product of two nonnegative definite Hermitian matrices is nonnegative definite.

Let us first assume that the nonnegative definite matrix $C^\pm$ is positive definite. We will see that the general case can be reduced to this one.

Now note that $Z_{e_j + \rho(e_q) - e, \omega_j - \rho(\omega_q)}$ is the inverse of the determinant of a positive definite matrix of the form:

$$D(j, q) = \begin{bmatrix} A(j) & -C \pm \\ -C \pm & A(q) \end{bmatrix}$$

with $[A(j)]_{u,v} = \lambda_u^{(\epsilon)} \delta_{u,v} - C_u^{(\epsilon)} e^{e_u^{(\epsilon)}}$ and $C^\pm_{u,v} = C_{u,p(v)}$.

It is enough to show that $\det(D(j, k))^{-1}$ can be expanded in series of products $\sum q_n(j) q_n(k)$ with $\sum |q_n(j)|^2 < \infty$.

As

$$D(j, q) = \begin{bmatrix} [C^\pm]^{(j)} & 0 \\ 0 & [C^\pm]^{(q)} \end{bmatrix} \begin{bmatrix} [C^\pm]^{(j)} & \frac{i}{2} A(j) [C^\pm]^{(j)} & -I \\ \frac{i}{2} A(j) [C^\pm]^{(j)} & -I \\ I \\\end{bmatrix} \begin{bmatrix} [C^\pm]^{(j)} & 0 \\ 0 & [C^\pm]^{(q)} \end{bmatrix}$$

the inverse of this determinant can be written

$$\det(C^\pm)^{-2} \det(F(j)) \det(F(q)^*) \det(I - \begin{bmatrix} 0 & F(j) \\ F(q)^* & 0 \end{bmatrix})^{-1}$$

with $F(j) = [C^\pm]^{(j)} A(j)^{-1} [C^\pm]^{(q)}$, or more simply:

$$F(j) = \det(A(j))^{-1} \det(A(q)^*)^{-1} \det(I - \begin{bmatrix} 0 & F(j) \\ F(q)^* & 0 \end{bmatrix})^{-1}.$$

Note that $A(j)^{-1}$ is also the Green function of the restriction to $X^+$ of the Markov chain associated with $e_j$, twisted by $\omega_j$. Therefore $A(j)^{-1} C^\pm = [C^\pm]^{(j)} F(j) [C^\pm]^{(q)}$ is the balayage kernel on $X^-$ defined by this Markov chain with an additional phase under the expectation produced by $\omega_j$. It is therefore clear that the eigenvalues of the matrices $A(j)^{-1} C^\pm$ and $F(j)$ are of modulus less than one and it follows that

$$\begin{bmatrix} 0 & F(j) \\ F(q)^* & 0 \end{bmatrix} = \begin{bmatrix} 0 & I \end{bmatrix} \begin{bmatrix} F(q)^* & 0 \\ 0 & F(j) \end{bmatrix}.$$
is a contraction. We can always assume it is a strict contraction, by adding a killing term we can let converge to zero once the inequality is proved.

If \( X^+ \) has only one point, \( 1 - F(j)F(q)^* \) which allows to conclude. Let us now treat the general case.

For any \( (n, m) \) matrix \( N \), and \( k = (k_1, \ldots, k_m) \in \mathbb{N}^m \), \( l = (l_1, \ldots, l_n) \in \mathbb{N}^n \), let \( N^{(k,l)} \) denote the \( (|k|, |l|) \) matrix obtained from by repeating \( k_i \) times each line \( i \); then \( l_j \) times each column \( j \).

We use the expansion

\[
\det(I - M)^{-1} = 1 + \sum_{|k|!} \text{Per}(M^{(k,k)})
\]

valid for any strict contraction \( M \) (Cf [56] and [57]).

Note that if \( X \) has 2d points, if we denote \( (k_1, \ldots, k_{2d}) \) by \( (k^+, k^-) \), with \( k^+ = (k_1, \ldots, k_d) \) and \( k^- = (k_{d+1}, \ldots, k_{2d}) \).

\[
\begin{bmatrix}
0 & F(j) \\
F(q)^* & 0 \\
\end{bmatrix}^{(k,k)} = \begin{bmatrix}
0 & F(j)^{(k^+, k^-)} \\
(F(q)^*)^{(k^-, k^+)} & 0 \\
\end{bmatrix}.
\]

But the all terms in the permanent of a \((2n, 2n)\) matrix of the form \( \begin{bmatrix} 0 & A \\ B^* & 0 \end{bmatrix} \) vanish unless the submatrices \( A \) and \( B \) are square matrices (not necessarily of equal ranks). Hence in our case, we necessary have \(|k^+| = |k^-|\), so that, \( A \) and \( B \) are \((n, n)\) matrices.

Then, the non zero terms in the permanent come from permutations exchanging \( \{1, 2, \ldots, n\} \) and \( \{n+1, \ldots, 2n\} \), which can be decomposed into a pair of permutations of \( \{1, 2, \ldots, n\} \). Therefore:

\[
\text{Per}\left( \begin{bmatrix} 0 & A \\ B^* & 0 \end{bmatrix} \right) = \text{Per}(A)\text{Per}(B^*)
\]

which concludes the proof in the positive definite case as

\[
\text{Per}(B^*) = \sum_{\tau \in S_n} \prod_{i=1}^{n} B^*_{\tau(i), i} = \sum_{\tau \in S_n} \prod_{i=1}^{n} B_{\tau(i), i} = \overline{\text{Per}(B)}.
\]

To treat the general case where \( C^\pm \) is only nonnegative definite, we can use use a passage to the limit or alternatively, the proposition 26 (or more precisely its extension including including a current) to reduce the sets \( X^+ \) and \( X^- \) to the support of \( C^\pm \).

To prove ii) let us first show the assumptions imply that the \( X^+ \times X^+ \) matrix \( G_{x,y}^\pm = G_{x,\rho(y)}^\pm \) is also nonnegative definite. Let us write \( G \) in the form

\[
\begin{bmatrix}
A & -C^\pm \\
-C^\pm & A \\
\end{bmatrix}^{-1}
\]

with \( A = M_\lambda - C \). Then
\[ G = \begin{bmatrix} A^{-\frac{1}{2}} & 0 \\ 0 & A^{-\frac{1}{2}} \end{bmatrix} \begin{bmatrix} I & -A^{-\frac{1}{2}} C^\pm A^{-\frac{1}{2}} \\ -A^{-\frac{1}{2}} C^\pm A^{-\frac{1}{2}} & I \end{bmatrix}^{-1} \begin{bmatrix} A^{-\frac{1}{2}} & 0 \\ 0 & A^{-\frac{1}{2}} \end{bmatrix}. \]

\( A^{-\frac{1}{2}} C^\pm A^{-\frac{1}{2}} \) is non-negative definite and as before, we can check it is a contraction since \( A^{-1} C^\pm \) is a balayage kernel.

Note that if a symmetric non-negative definite matrix \( K \) has eigenvalues \( \mu_i \), the eigenvalues of the symmetric matrix \( E \) defined by

\[ \begin{bmatrix} I & -K \\ -K & I \end{bmatrix}^{-1} = \begin{bmatrix} D & E \\ E & D \end{bmatrix} \]

are easily seen (exercise) to be \( \frac{\mu_i}{1-\mu_i^2} \). Taking \( K = A^{-\frac{1}{2}} C^\pm A^{-\frac{1}{2}} \), it follows that the symmetric matrix \( E \), (and in our particular case \( G^\pm = A^{-\frac{1}{2}} E A^{-\frac{1}{2}} \)) is non-negative definite.

To finish the proof, let us take \( \Sigma \) of the form \( \sum \lambda_j e^{\langle \phi, \chi_j \rangle} \). Then

\[ \mathbb{E}_\phi(\Sigma(\phi)\Sigma(\rho(\phi))) = \sum \lambda_j \lambda_k \mathbb{E}_\phi(e^{\langle \phi, \chi_j \rangle + \langle \rho, \chi_k \rangle}) = \sum \lambda_j \lambda_k e^{\frac{1}{2}(\langle \chi_j, G^\pm \chi_k \rangle \lambda_k e^{\frac{1}{2}(\chi_j, G^\pm \chi_k)})} \]

(using that \( G^\pm \) is symmetric).

As \( G^\pm \) is positive definite, we can conclude since \( e^{\frac{1}{2}(\langle \chi_j, G^\pm \chi_k \rangle \lambda_k e^{\frac{1}{2}(\chi_j, G^\pm \chi_k)})} \), \( w \) denoting the Gaussian field on \( X^+ \) with covariance \( G^\pm \).

To prove iii), note that the transfer impedance matrix can be decomposed as \( G \). In particular, \( K_{i,j} = -(K^\pm_{\xi_i,\xi_j})^2 \), with

\[ K^\pm_{(x,y),(u,v)} = K^{(x,y),\rho(u,v)} = G^\pm(x,u) + G^\pm(y,v) - G^\pm(x,v) - G^\pm(y,u). \]

Then, using again the Gaussian vector \( w \), and the Wick squares of its components:

\[ (K^\pm_{(x,y),(u,v)})^2 = E(\langle w_u - w_v \rangle^2 \langle w_x - w_y \rangle^2). \]

**Remark 25.** a) If \( U_j \) are unitary representations with \( d_U = d \) and such that \( U_j \) \( x,y \) is the identity outside \( X^+ \times X^+ \), i) can be extended to variables of the form \( \sum \lambda_j B_{(d)}^{\epsilon, \xi_j, U_j} \) and to the \( \sigma \)-field they generate.

b) The property i) can be also derived from the reflection positivity of the free field ii) and by remark 13. Then it can also be proved that for any set of points \( \{ x_j \} \) in \( X^+ \), the matrix \( \mathbb{E}(\bar{\Phi} \bar{L}_d \Phi \rho \bar{L}_d N_{x_j, \rho x_j}) \) is non-negative definite.

c) In the case where \( \alpha \) is a half integer, by remark 11, the reflection positivity of the free field ii), implies i) holds also for any half integer \( \alpha \) provided that \( \Phi \in \sigma(\bar{\Phi}_x, x \in X^+) \cup \sigma(N^{(\alpha)}_{x,y} + N^{(\alpha)}_{y,x}, x, y \in X^+) \).

**Exercise 41.** Prove the above remarks.
Remark 26. If there exists a partition of $X$: $X = X^+ \cup X^- \cup X^0$, and an involution $\rho$ on $X$ such that:

a) $e$ and $X^0$ are $\rho$-invariant.

b) $\rho(X^\pm) = X^\mp$

c) $X^+$ and $X^-$ are disconnected.

Then the assumptions of the previous theorem are satisfied for the trace on $X^+ \cup X^-$. Moreover, if $X^0 \times X^0$ does not contain any edge of the graph, the assertion i) of theorem 7 holds for the non disjoint sets $X^+ \cup X^0$ and $X^- \cup X^0$. More precisely, i), holds for $\Phi$ in $\sigma(L_d^2, x \in X^+ \cup X^0) \setminus \sigma(N_{x,y}, x,y \in X^+ \cup X^0)$. It is enough to apply the theorem to the graph obtained by duplication of each point $x_0$ in $X^0$ into $(x_0^+, x_0^-)$, with $x_0^\pm$ connected to points in $X^\pm$ and connected together by conductances $C_{x_0^+, x_0^-}$ we can let increase to infinity.

9.2 A counter example

Let show that the reflection positivity does not hold under $\mu$ for loop functionals. Therefore, it will be clear it does not hold for small $\alpha$. We will consider functionals of the occupation field.

Consider the graph formed by a cube $\pm a, \pm b, \pm c, \pm d$ and the mid-points $\pm \alpha, \pm \beta, \pm \gamma, \pm \delta$ of the sides $\pm ab, \pm cd, \pm ac, \pm bd$. The edges are given by the sides of the cube, as in the picture.

![Fig. 9.1 A counter example](image)
We can take for example all conductances and killing rates to be equal. Then the symmetry \( \rho : x \to -x \) defines an involution satisfying the assumption of theorem 7. Define the set of loops \( A = \{ l, \hat{t}^\alpha \hat{t}^\beta > 0 \} \), \( A' = \{ l, \hat{t}^\alpha = \hat{t}^\beta = 0 \} \), \( B = \{ l, \hat{t}^\gamma \hat{t}^\delta > 0 \} \) and \( B' = \{ l, \hat{t}^\gamma = \hat{t}^\delta = 0 \} \). Note that \( A \cap B' \cap \rho(A) \cap \rho(B') \), \( A' \cap B \cap \rho(A') \cap \rho(B) \) are empty. But \( A' \cap B \cap \rho(A) \cap \rho(B') \) and \( A \cap B' \cap \rho(A') \cap \rho(B) \) are not (consider the loop \( aab(-b)(-\delta)(-c)d(\gamma)(-a)a \)).

Then, if we set \( \Phi = 1_{A \cap B'} - 1_{A' \cap B} \), it is clear that

\[
\mu(\Phi, \Phi \circ \rho) = -2\mu(A \cap B' \cap \rho(A') \cap \rho(B)) < 0.
\]

### 9.3 Physical Hilbert space and time shift:

We will now work under the assumptions of remark 26, namely, without assuming that \( X = X^+ \cup X^- \).

The following results and terminology are inspired by methods of constructive Quantum field theory (Cf \([50]\) and \([13]\)).

Let \( \mathcal{H}^+ \) be the space of square integrable functions in \( \sigma((\mathcal{L}_1^e, x \in X^+) \setminus \sigma(N_{x,y}^{(1)}, x, y \in X^+) \), equipped with the scalar product \( \langle \Phi, \Psi \rangle_{\mathcal{H}} = \mathbb{E}(\Phi(\mathcal{L}_1)\Psi(\rho(\mathcal{L}_1))) \) Note that \( \langle \Phi, \Phi \rangle_{\mathcal{H}} \leq \mathbb{E}(\Phi^2(\mathcal{L}_1)) \) by Cauchy-Schwartz inequality.

Let \( \mathcal{N} \) be the subspace \( \{ \Psi \in \mathcal{H}^+, \mathbb{E}(\Psi(\mathcal{L}_1)\Psi(\rho(\mathcal{L}_1))) = 0 \} \) and \( \mathcal{H} \) the closure (for the topology induced by this scalar product) of the quotient space \( \mathcal{H}^+ / \mathcal{N} \) (which can be called the physical Hilbert space). We denote \( \Phi^\sim \) the equivalence class of \( \Phi \), \( \mathcal{H} \) is equipped with the scalar product defined unambiguously by \( \langle \Phi^\sim, \Psi^\sim \rangle_{\mathcal{H}} = \langle \Phi, \Psi \rangle_{\mathcal{H}} \).

Assume \( X \) is of the form \( X_0 \times \mathbb{Z} \) (space \( \times \) time) and let \( \theta \) be the natural time shift. We assume \( \theta \) preserves \( c \), i.e. that conductances and \( \kappa \) are \( \theta \)-invariant. We define \( \rho \) by \( \rho(x_0, n) = (x_0, -n) \) and assume \( e \) is \( \rho \)-invariant. Note that \( \theta(X^+) \subseteq X^+ \) and \( \rho \theta = \theta^{-1} \rho \). The transformations \( \rho \) and \( \theta \) induce a transformations on loops that preserves \( \mu \), and \( \theta \) induces a linear transformation of \( \mathcal{H}^+ \). Moreover, given any \( F \) in \( \mathcal{N} \), \( F \circ \theta \in \mathcal{N} \), as \( (F \circ \theta, F \circ \theta)_{\mathcal{H}} \) is nonegative and equals

\[
\mathbb{E}(F \circ \theta(\mathcal{L}_1)F \circ \theta(\rho(\mathcal{L}_1))) = \mathbb{E}(F(\theta(\mathcal{L}_1))F(\rho \circ \theta^{-1}(\mathcal{L}_1)) = \mathbb{E}(F(\theta^2(\mathcal{L}_1))F(-\theta(\mathcal{L}_1))
\]

which vanishes.
9.3 Physical Hilbert space and time shift:

**Proposition 30.** There exist a self adjoint contraction of $\mathcal{H}$, we will denote $\Pi^{(\theta)}$ such that $[\Phi \circ \theta] \sim = \Pi^{(\theta)}(\Phi \sim)$.

**Proof.** The existence of $\Pi^{(\theta)}$ follows from the last observation made above. As $\theta$ preserves $\mu$, it follows from the identity $\rho \theta = \theta^{-1} \rho$ that

$$
\langle F \circ \theta, G \rangle_{\mathcal{H}} = \mathbb{E}(F(\theta(L_1)) G(\rho(L_1)) = \mathbb{E}(F(L_1) G(\rho \circ \theta^{-1}(L_1))) = \mathbb{E}(F(L_1) G(\theta \circ \rho(L_1))) = \langle G \circ \theta, F \rangle_{\mathcal{H}}.
$$

Therefore, $\Pi^{(\theta)}$ is self adjoint on $\mathcal{H}^+/\mathcal{N}$. To prove that it is a contraction, it is enough to show that $\langle F \circ \theta, F \circ \theta \rangle_{\mathcal{H}} \leq \langle F, F \rangle_{\mathcal{H}}$ for all $F \in \mathcal{H}^+$. But as shown above, $\langle F \circ \theta, F \circ \theta \rangle_{\mathcal{H}} = \langle F \circ \theta^2, F \rangle_{\mathcal{H}} \leq \sqrt{\langle F \circ \theta^2, F \circ \theta^2 \rangle_{\mathcal{H}} \langle F, F \rangle_{\mathcal{H}}}$.

By recursion, it follows that:

$$
\langle F \circ \theta, F \circ \theta \rangle_{\mathcal{H}} \leq \left( \langle F \circ \theta^{2^n}, F \circ \theta^{2^n} \rangle_{\mathcal{H}} \right)^{\frac{1}{2^n}} \langle F, F \rangle_{\mathcal{H}}^{1-2^{-n}}
$$

As $\langle F \circ \theta^{2^n}, F \circ \theta^{2^n} \rangle_{\mathcal{H}} \leq (\mathbb{E}(F^2(L_1)))^{2^{-n}}$ which converges to 1 as $n \to \infty$, the inequality follows.

For all $n \in \mathbb{Z}$, the symmetry $\rho^{(n)} = \theta^{-n} \rho \theta^n$ allows to define spaces $\mathcal{H}^{(n)}$ isometric to $\mathcal{H}$. These isometries can be denoted by the shift $\theta^n$. For $n > m$, $j_{n,m} = \theta^n [\Pi^{(\theta)}]^{n-m} \theta^{-n}$ is a contraction from $\mathcal{H}^{(n)}$ into $\mathcal{H}^{(m)}$. 

Chapter 10
The case of general symmetric Markov processes

10.1 Overview

We now explain briefly how some of the above results can be extended to symmetric Markov processes on continuous spaces. The construction of the loop measure as well as a lot of computations can be performed quite generally, using Markov processes or Dirichlet space theory (Cf for example [12]). It works as soon as the bridge or excursion measures $\mathbb{P}_t^{x,y}$ can be properly defined. The semigroup should have a density with respect to the duality measure given by a locally integrable kernel $p_t(x,y)$. This is very often the case in examples of interest, especially in finite dimensional spaces.

The main issue is to determine whether the results which have been developed in the previous chapters still hold, and precisely in what sense.

Loop hitting distributions

An interesting result is formula 4.9, and its reformulation in proposition 27. The expression on the left-hand side is well defined but the determinants appearing in 4.9 are not. In the example of Brownian motion killed at the exit of a bounded domain, Weyl asymptotics show that the divergences appearing on the right-hand side of 4.9 may cancel. And in fact, the right-hand side in 27 can be well defined in terms of the densities of the hitting distributions of $F_1$ and $F_2$ with respect to their capacitary measures, which allow to take the trace. A direct proof, using Brownian motion and classical potential theory, should be easy to provide, along the lines of the solution of exercise 31.
Determinantal processes

Another result of interest involves the point process defined by the points connected to the root of a random spanning tree. In the case of an interval of \( Z \), we get a process with independent spacings. For one dimensional diffusions, this point process with independent spacings has clearly an analogue which is the determinantal process with independent spacings (See [51]) defined by the kernel \( \sqrt{k(x)}G(x, y)\sqrt{k(y)} \) (\( k \) being the killing rate and \( G \) the Green function). For one dimensional Brownian motion killed at a constant rate, we recover Macchi point process (Cf [32]).

It suggests that this process (together with the loop ensemble \( \mathcal{L}_1 \)) can be constructed by various versions of Wilson algorithm adapted to the real line. A similar result holds on \( Z \) or \( N \), where the natural ordering can be used to construct the spanning tree by Wilson algorithm, starting at 0.

For constant killing rate, \( \sqrt{k(x)}G(x, y)\sqrt{k(y)} \) can be expressed as \( \rho \exp(-|x - y|/a) \), with \( a, \rho > 0 \) and \( 2\rho a < 1 \), the law of the spacings has therefore a density proportional to \( e^{-\frac{x}{\rho} \sinh(\sqrt{1-2\rho a} x)} \) (Cf [32]), which appears to be the convolution of two exponential distributions of parameters \( \frac{1}{a}(\sqrt{1-2\rho a} + 1) \) and \( \frac{1}{a}(-\sqrt{1-2\rho a} + 1) \). A similar result holds on \( Z \) with geometric distributions. The spanning forest obtained by removing the cemetery point is composed of trees made of pair of intervals joining at points directly connected to the cemetery, whose length are independent with laws given by these (different!) exponential distributions. The separating points between these trees form a determinantal process intertwinned with the previous one (the roots directly connected to the cemetery point), with the same distribution. There are two equally probable intertwinning configurations on \( \mathbb{R} \), and only one in \( \mathbb{R}^+ \) or \( \mathbb{R}^- \).

Occupation field and continuous branching

Let us consider more closely the occupation field \( \hat{l} \). The extension is rather straightforward when points are not polar. We can start with a Dirichlet space of continuous functions and a measure \( m \) such that there is a mass gap. Let \( P_t \) denote the associated Feller semigroup. Then the Green function \( G(x, y) \) is well defined as the mutual energy of the Dirac measures \( \delta_x \) and \( \delta_y \) which have finite energy. It is the covariance function of a Gaussian free field \( \phi(x) \), and the field \( \frac{1}{2}\phi(x)^2 \) will have the same distribution as the field \( \hat{L}_t \) of local times of the Poisson process of random loops whose intensity is given by the loop measure defined by the semigroup \( P_t \). This will applies to
examples related to one-dimensional Brownian motion (or to Markov chains on countable spaces).

Remark 27. When we consider Brownian motion on the half line, the associated occupation field $\hat{L}_\alpha$ is a continuous branching process with immigration, as in the simple random walk case considered above.

Generalized fields and renormalization

When points are polar, one needs to be more careful. We will consider only the case of the two and three dimensional Brownian motion in a bounded domain $D$ killed at the boundary, i.e. associated with the classical energy with Dirichlet boundary condition. The Green function does not induce a trace class operator but it is still Hilbert-Schmidt which allows us to define renormalized determinants $\text{det}_2$ (Cf [49]).

If $A$ is a symmetric Hilbert Schmidt operator, $\text{det}_2(I + A)$ is defined as $\prod(1 + \lambda_i)e^{-\lambda_i}$ where $\lambda_i$ are the eigenvalues of $A$.

The Gaussian field (called free field) whose covariance function is the Green function is now a generalized field: Generalized fields are not defined pointwise but have to be smeared by a compactly supported continuous test function $f$. Still $\phi(f)$ is often denoted $\int \phi(x)f(x)dx$.

The Wick powers $\phi^n$ of the free field can be defined as generalized fields by approximation as soon as the $2n$-th power of the Green function, $G(x,y)^{2n}$ is locally integrable (Cf [50]). This is the case for all $n$ for the two dimensional Brownian motion killed at the exit of an open set, as the Green function has only a logarithmic singularity on the diagonal, and for $n = 2$ in dimension three as the singularity is of the order of $\frac{1}{\|x-y\|}$. More precisely, taking for example $\pi^x_\varepsilon(dy)$ to be the normalized area measure on the sphere of radius $\varepsilon$ around $x$, $\phi(\pi^x_\varepsilon)$ is a Gaussian field with variance $\sigma^x_\varepsilon = \int G(z,z')\pi^x_\varepsilon(dz)\pi^x_\varepsilon(dz')$. Its Wick powers are defined with Hermite polynomials as we did previously:

$\phi(\pi^x_\varepsilon)^n := (\sigma^x_\varepsilon)^n H_n(\frac{\phi(\pi^x_\varepsilon)}{\sqrt{\sigma^x_\varepsilon}})$. Then one can see that, for any compactly supported continuous function $f$, $\int f(x) : \phi(\pi^x_\varepsilon)^n : dx$ converges in $L^2$ towards a limit called the $n$-th Wick power of the free field evaluated on $f$ and denoted $\phi^n : (f)$. Moreover, $E(\phi^n : (f) : \phi^n : (h)) = \int G^{2n}(x,y)f(x)h(y)dxdy$.

In these cases, we can extend the statement of theorem 2 to the renormalized occupation field $\hat{L}_\pi$ and the Wick square $\phi^2$ of the free field.
10.2 Isomorphism for the renormalized occupation field

Let us explain this in more detail in the Brownian motion case. Let $D$ be an open subset of $\mathbb{R}^d$ such that the Brownian motion killed at the boundary of $D$ is transient and has a Green function. Let $p_t(x,y)$ be its transition density and $G(x,y) = \int_0^\infty p_t(x,y)dt$ the associated Green function. The loop measure $\mu$ was defined in [20] as

$$\mu = \int_D \int_0^\infty \frac{1}{t} \mathbb{P}_t^{x,x} dt$$

where $\mathbb{P}_t^{x,x}$ denotes the (non normalized) bridge measure of duration $t$ such that if $0 \leq t_1 \leq \ldots \leq t_h \leq t$,

$$\mathbb{P}_t^{x,x}(\xi(t_1) \in dx_1, ..., \xi(t_h) \in dx_h) = p_t(x,x)p_{t_2-t_1}(x_1,x_2)\ldots p_{t_h-t_{h-1}}(x_{h-1},x_h)dx_1\ldots dx_h$$

(the mass of $\mathbb{P}_t^{x,x}$ is $p_t(x,x)$). Note that $\mu$ is a priori defined on based loops but it is easily seen to be shift-invariant.

For any loop $l$ indexed by $[0,T(l)]$, define the measure $\hat{\mu} = \int_0^{T(l)} \delta_{l(s)} ds$: for any Borel set $A$, $\hat{\mu}(A) = \int_0^{T(l)} 1_A(l_s) ds$.

**Lemma 2.** For any non-negative function $f$,

$$\mu(\langle \hat{\mu}, f \rangle^n) = (n-1)! \int G(x_1,x_2)f(x_2)G(x_2,x_3)f(x_3)\ldots G(x_n,x_1)f(x_1) \prod_i^nx_i.$$

**Proof.** From the definition of $\mu$ and $\hat{\mu}$, $\mu(\langle \hat{\mu}, f \rangle^n)$ equals:

$$n! \int \int_{\{0<s_1<\ldots<s_n<t\}} \frac{1}{t} f(x_1)\ldots f(x_n)p_{t_1}(x_1,x_1)\ldots p_{t_n}(x_n,x_n) \prod dt_1 dx_1 dt dx$$

$$= n! \int \int_{\{0<s_1<\ldots<s_n<t\}} \frac{1}{t} f(x_1)\ldots f(x_n)p_{t_2-t_1}(x_1,x_2)\ldots p_{t_n-t_{n-1}}(x_{n-1},x_n) \prod dt_1 dx_1 dt.$$

Performing the change of variables $v_2 = t_2 - t_1$, ..., $v_n = t_n - t_{n-1}$, $v_1 = t_1 + t - t_n$, and $v = t_1$, we obtain:

$$n! \int \int_{\{0<v_1<\ldots<v_n\}} \frac{1}{v_1 + \ldots + v_n} f(x_1)\ldots f(x_n)p_{v_1}(x_1,x_2)\ldots p_{v_n}(x_n,x_1) \prod dv_1 dx_1 dv$$

$$= n! \int \int_{\{0<v_1\}} \frac{v_1}{v_1 + \ldots + v_n} p_{v_2}(x_1,x_2)\ldots p_{v_n}(x_n,x_1) \prod f(x_i) dv_i dx_i$$

$$= (n-1)! \int \int_{\{0<v_1\}} f(x_1)\ldots f(x_n)p_{v_2}(x_1,x_2)\ldots p_{v_n}(x_n,x_1) \prod dv_i dx_i$$

(as we get the same formula with any $v_i$ instead of $v_1$)

$$= (n-1)! \int G(x_1,x_2)f(x_2)G(x_2,x_3)f(x_3)\ldots G(x_n,x_1)f(x_1) \prod dx_i.$$
One can define in a similar way the analogous of multiple local times, and get for their integrals with respect to $\mu$ a formula analogous to the one obtained in the discrete case.

Let $G$ denote the operator on $L^2(D, dx)$ defined by $G$. Let $f$ be a non-negative continuous function with compact support in $D$.

Note that $\langle \hat{\ell}, f \rangle$ is $\mu$-integrable only in dimension one as then, $G$ is locally trace class. In that case, using for all $x$ an approximation of the Dirac measure at $x$, local times $\hat{\ell}_x$ can be defined in such a way that $\langle \hat{\ell}, f \rangle = \int \hat{\ell}^x f(x) dx$.

$\langle \hat{\ell}, f \rangle$ is $\mu$-square integrable in dimensions one, two and three, as $G$ is Hilbert-Schmidt if $D$ is bounded, since $\int\int_{D \times D} G(x, y)^2 dx dy < \infty$, and otherwise locally Hilbert-Schmidt.

**N.B.:** Considering distributions $\chi$ such that $\int\int (G(x, y))^2 \chi(dx) \chi(dy)$ is finite, we could see that $\langle \hat{\ell}, \chi \rangle$ can be defined by approximation as a square integrable variable and $\mu \left( \langle \hat{\ell}, \chi \rangle^2 \right) = \int (G(x, y))^2 \chi(dx) \chi(dy)$.

Let $z$ be a complex number such that $\text{Re}(z) > 0$.

Note that $e^{-z \langle \hat{\ell}, f \rangle} + z \langle \hat{\ell}, f \rangle - 1$ is bounded by $\frac{|z|^2}{2} \langle \hat{\ell}, f \rangle^2$ and expands as an alternating series $\sum_2^\infty \frac{z^n}{n!} \left(-\langle \hat{\ell}, f \rangle\right)^n$, with

$$\left| e^{-z \langle \hat{\ell}, f \rangle} - 1 - \sum_1^N \frac{z^n}{n!} \left(-\langle \hat{\ell}, f \rangle\right)^n \right| \leq \frac{|z|^{N+1} \langle \hat{\ell}, f \rangle |^{N+1}}{(N+1)!}.$$  

Then, for $|z|$ small enough, it follows from the above lemma that

$$\mu \left( e^{-z \langle \hat{\ell}, f \rangle} + z \langle \hat{\ell}, f \rangle - 1 \right) = \sum_2^\infty \frac{z^n}{n} \text{Tr}(-(M_{\sqrt{\mathcal{T}}} G M_{\sqrt{\mathcal{T}}})^n).$$

As $M_{\sqrt{\mathcal{T}}} G M_{\sqrt{\mathcal{T}}}$ is Hilbert-Schmidt the renormalized determinant $\det_2(I + z M_{\sqrt{\mathcal{T}}} G M_{\sqrt{\mathcal{T}}})$ is well defined and the second member writes $-\log(\det_2(I + z M_{\sqrt{\mathcal{T}}} G M_{\sqrt{\mathcal{T}}}))$.

Then the identity

$$\mu(e^{-z \langle \hat{\ell}, f \rangle} + z \langle \hat{\ell}, f \rangle - 1) = -\log(\det_2(I + z M_{\sqrt{\mathcal{T}}} G M_{\sqrt{\mathcal{T}}}))$$

extends, as both sides are analytic as locally uniform limits of analytic functions, to all complex values with positive real part.

The renormalized occupation field $\tilde{L}_\alpha$ is defined as the compensated sum of all $\hat{\ell}$ in $L_\alpha$ (formally, $\tilde{L}_\alpha = \hat{L}_\alpha - \int_0^T (\delta_t, ds\mu(dl))$). More precisely, we apply a standard argument used for the construction of Levy processes, setting:
Brownian "loop soup" (cf. invariance of the Brownian trajectories that a similar property holds for the Lévy exponent of a Markov process). Assume $\lambda > 0$ is a continuous function and $\alpha > 0$. The renormalized occupation field $\widetilde{E}(\alpha, f)$ converges a.s. and in $L^2$ as

$$\mathbb{E}\left( \sum_{\gamma \in \mathcal{L}_\alpha} \left( 1_{\{T > \varepsilon\}} \int_0^T f(\gamma_s) ds - \alpha \mu(1_{\{T > \varepsilon\}}) \int_0^T f(\gamma_s) ds \right) \right)$$

and $\mathbb{E}\left( \widetilde{E}(\alpha, f) \right)^2 = \text{Tr}(\mathcal{K}^2)$. Note that if we fix $f$, $\alpha$ can be considered as a time parameter and $\langle \widetilde{E}(\alpha, f) \rangle$ are Levy processes with discrete positive jumps approximating a Levy process with positive jumps $\langle \widetilde{E}(\alpha, f) \rangle$. The Levy exponent $\mu(1_{\{T > \varepsilon\}})(e^{-\langle \widetilde{E}(\alpha, f) \rangle} + \langle \widetilde{E}(\alpha, f) \rangle - 1)$ converges towards the Levy exponent of $\langle \widetilde{E}(\alpha, f) \rangle$ which is $\mu((e^{-\langle \widetilde{E}(\alpha, f) \rangle} + \langle \widetilde{E}(\alpha, f) \rangle - 1)$ and, from the identity $E(e^{-\langle \widetilde{E}(\alpha, f) \rangle} = e^{-\alpha \mu(e^{-\langle \widetilde{E}(\alpha, f) \rangle} + \langle \widetilde{E}(\alpha, f) \rangle - 1)$, we get the

**Theorem 8.** Assume $d \leq 3$. Denoting $\widetilde{E}(\alpha)$ the compensated sum of all $\tilde{t}$ in $\mathcal{L}_\alpha$, we have

$$\mathbb{E}(e^{-\langle \widetilde{E}(\alpha, f) \rangle}) = \det_2 \left( I + \mathcal{K}^2 \mathcal{G}(\mathcal{K})^2 \right)^{-\alpha}.$$ 

Moreover $e^{-\langle \widetilde{E}(\alpha, f) \rangle} \to e^{-\langle \widetilde{E}(\alpha, f) \rangle}$ a.s. and in $L^1$ towards $e^{-\langle \widetilde{E}(\alpha, f) \rangle}$.

Considering distributions of finite $G^2$-energy $\chi$ (i.e. such that $\int (G(x, y))^2 \chi(dx) \chi(dy) < \infty$), we can see that $\langle \widetilde{E}(\alpha, \chi) \rangle$ can be defined by approximation as $\lim_{\varepsilon \to 0} \langle \langle \widetilde{E}(\alpha, \chi) \rangle \rangle$ and

$$\mathbb{E}\left( \langle \widetilde{E}(\alpha, \chi) \rangle^2 \right) = \alpha \int (G(x, y))^2 \chi(dx) \chi(dy).$$

Specializing to $\alpha = \frac{k}{2}$, $k$ being any positive integer we have:

**Corollary 7.** The renormalized occupation field $\widetilde{E}^{\frac{1}{2}}$ and the Wick square $\frac{1}{2} : \sum_1^k \phi^2$ have the same distribution.

If $\Theta$ is a conformal map from $D$ onto $\Theta(D)$, it follows from the conformal invariance of the Brownian trajectories that a similar property holds for the Brownian "loop soup" (cf. [20]). More precisely, if $c(x) = \text{Jacobian}_x(\Theta)$ and, given a loop $l$, if $T^c(l)$ denotes the reparametrized loop $l_{c,x}$, with $\int_0^l c(l_u) du =$
10.3 Renormalized powers

$s$, the configuration $ΘT^c(Ł_α)$ is a Brownian loop soup of intensity parameter $α$ on $Θ(D)$. Then we have the following:

**Proposition 31.** $Θ(Ł_α)$ is the renormalized occupation field on $Θ(D)$.

**Proof.** We have to show that the compensated sum is the same if we perform it after or before the time change. For this it is enough to check that

$$E(\left[ \sum_{γ \in Ł_α} (1_{\{τT > η\}}1_{\{T ≤ ε\}} \int_0^T f(γ_s)ds - α \int (1_{\{τT > η\}}1_{\{T ≤ ε\}} \int_0^T f(γ_s)ds)μ(δγ))^2 \right]^2)$$

$$= α \int (1_{\{τT > η\}}1_{\{T ≤ ε\}} \int_0^T f(γ_s)ds)^2 μ(δγ)$$

and

$$E(\left[ \sum_{γ \in Ł_α} (1_{\{τT > ε\}}1_{\{T ≤ η\}} \int_0^T f(γ_s)ds - α \int (1_{\{τT > ε\}}1_{\{T ≤ η\}} \int_0^T f(γ_s)ds)μ(δγ))^2 \right]^2)$$

$$= α \int (1_{\{τT > ε\}}1_{\{T ≤ η\}} \int_0^T f(γ_s)ds)^2 μ(δγ)$$

converge to zero as $ε$ and $η$ go to zero. It follows from the fact that:

$$∫ [1_{\{T ≤ ε\}} \int_0^T f(γ_s)ds]^2 μ(δγ)$$

and

$$∫ [1_{\{τT ≤ η\}} \int_0^T f(γ_s)ds]^2 μ(δγ)$$

converge to 0. The second follows easily from the first if $c$ is bounded away from zero. We can always consider the ”loop soups” in an increasing sequence of relatively compact open subsets of $D$ to reduce the general case to that situation.

As in the discrete case (see corollary 3), we can compute product expectations. In dimension $≤ 3$, for $f_j$ continuous functions with compact support in $D$:

$$E(\left( Ł_α, f_1 \right) ... \left( Ł_α, f_k \right)) = ∫ Per_α^0(G(x_l, x_m), 1 ≤ l, m ≤ k) \prod f_j(x_j)dx_j.$$  

(10.1)

## 10.3 Renormalized powers

In dimension one, as in the discrete case, powers of the occupation field can be viewed as integrated self intersection local times. In dimension two, renormalized powers of the occupation field, also called renormalized self intersections local times can be defined, using renormalization polynomials
derived from the polynomials $Q_k^{\alpha,\sigma}$ defined in section 4.2. The polynomials $Q_k^{\alpha,\sigma}$ cannot be used directly as pointed out to me by Jay Rosen. See Dynkin [9], [10], [23], [34] for such definitions and proofs of convergence in the case of paths.

Assume $d = 2$. Let $\pi_x^\varepsilon(dy)$ be the normalized arclength on the circle of radius $\varepsilon$ around $x$, and set $\sigma_x^\varepsilon = \int G(y,z)\pi_x^\varepsilon(dy)\pi_z^\varepsilon(dz)$.

As the distance between $x$ and $y$ tends to 0, $G(x,y)$ is equivalent to $G_0(x,y) = \frac{1}{2\varepsilon} \log(\|x-y\|)$ and moreover, $G(x,y) = G_0(x,y) - H^D(x,dz)G_0(z,y)$, $H^D$ denoting the Poisson kernel on the boundary of $D$.

Let $G_{x,x}^{t,\varepsilon}$ (respectively $G_{y,y}^{t,\varepsilon}$, $G_{x,y}^{t,\varepsilon}$, $G_{x,y}^{t,\varepsilon}$) denote the operator from $L^2(\pi_x^\varepsilon)$ into $L^2(\pi_x^\varepsilon)$ (respectively $L^2(\pi_y^\varepsilon)$ into $L^2(\pi_y^\varepsilon)$, $L^2(\pi_x^\varepsilon)$ into $L^2(\pi_x^\varepsilon)$, $L^2(\pi_y^\varepsilon)$ into $L^2(\pi_y^\varepsilon)$) induced by the restriction of the Green functions to the circle pairs. Let $\iota_{x,y}$ be the isometry $L^2(\pi_x^\varepsilon)$ into $L^2(\pi_y^\varepsilon)$ induced by the natural map between the circles.

$G_{x,x}^{t,\varepsilon}$ and $G_{y,y}^{t,\varepsilon}$ are clearly Hilbert Schmidt operators, while the products $G_{x,y}^{t,\varepsilon}(\iota_{x,y})$ and $G_{y,x}^{t,\varepsilon}(\iota_{x,y})$ are trace-class.

We define the renormalization polynomials via the following generating function:

$$q_{x,x,\alpha}(t,u) = e^\frac{-tu}{\pi^\alpha} \det 2(1 + \frac{t}{1+\sigma_x^\varepsilon})G_{x,x}^{t,\varepsilon,\alpha}(t,u)$$

This generating function is new to our knowledge but one should note that the generating functions of the polynomials $Q_k^{\alpha,\sigma}$ can be written $e^\frac{-tu}{\pi^\alpha}(1 - \frac{\varepsilon^\alpha t^2}{1+\sigma_x^\varepsilon})$ and therefore has the same form.

Define the renormalisation polynomials $Q_k^{x,\varepsilon,\alpha}$ by:

$$\sum t^k Q_k^{x,\varepsilon,\alpha}(u) = q_{x,x,\alpha}(t,u)$$

The coefficients of $Q_k^{x,\varepsilon,\alpha}$ involve products of terms of the form

$$Tr([G_{x,x}^{t,\varepsilon}]^m) = \int G(y_1,y_2)G(y_2,y_3)\cdots G(y_m,y_1)\prod_1^m \pi_x^\varepsilon(dy_i)$$

which are different from $(\sigma_x^\varepsilon)^m$ (but both are equivalent to $\left[\frac{-\log(\varepsilon)}{\pi}\right]^m$ as $\varepsilon \to 0$).

We have the following

**Theorem 9.** For any bounded continuous function $f$ with compact support,

$$\int f(x)Q_k^{x,\varepsilon,\alpha}(\tilde{L}_x^\alpha,\pi_x^\varepsilon)dx$$

converges in $L^2$ towards a limit denoted $\langle \tilde{L}_x^\alpha, f \rangle$ and

$$E(\langle \tilde{L}_x^\alpha, f \rangle \langle \tilde{L}_y^\alpha, h \rangle) = \delta_{l,k} \frac{\alpha(\alpha+1)\cdots(\alpha+k-1)}{k!} \int G^{2k}(x,y)f(x)h(y)dxdy.$$ 

**Proof.** The idea of the proof can be understood by trying to prove that

$$E(\int f(x)Q_k^{x,\varepsilon,\alpha}(\tilde{L}_x^\alpha,\pi_x^\varepsilon)dx)^2$$
remains bounded as $\varepsilon$ decreases to zero. One should expand this expression in terms of sums of integrals of products of Green functions and check that cancellations analogous to the the combinatorial identities (4.7) imply the cancelation of the logarithmic divergences.

These cancellations become apparent if we compute

$$(1) = \mathbb{E}(q_{x,x',a}(t, (\widetilde{L}_a, \pi^x_\varepsilon))q_{y,x',a}(s, (\widetilde{L}_a, \pi^{y}_{\varepsilon'})))$$

which is well defined for $s$ and $t$ small enough. As the measures $\pi^x_\varepsilon$ and $\pi^{y}_{\varepsilon'}$ are mutually singular $L^2(\pi^x_\varepsilon + \pi^{y}_{\varepsilon'})$ is the direct sum of $L^2(\pi^x_\varepsilon)$ and $L^2(\pi^{y}_{\varepsilon'})$, and any operator on $L^2(\pi^x_\varepsilon + \pi^{y}_{\varepsilon'})$ can be written as a matrix $\begin{pmatrix} A & B \\ C & D \end{pmatrix}$ where $A$ (respectively $D, B, C$) is an operator from $L^2(\pi^x_\varepsilon)$ into $L^2(\pi^{y}_{\varepsilon'})$ (respectively $L^2(\pi^{y}_{\varepsilon'})$ into $L^2(\pi^x_\varepsilon)$, $L^2(\pi^x_\varepsilon)$ into $L^2(\pi^{y}_{\varepsilon'})$, $L^2(\pi^{y}_{\varepsilon'})$ into $L^2(\pi^x_\varepsilon)$).

Theorem 8 can be proved in the same way for the Brownian motion time changed by the inverse of the sum of the additive functionals defined by $\pi^x_\varepsilon$ and $\pi^{y}_{\varepsilon'}$ (its Green function is the restriction of $G$ to the union of the two circles. Alternatively, one can extend theorem 8 to measures to get the same result). Applying this to the function equal to $t$ (respectively $s$) on the circle of radius $\varepsilon$ around $x$ (respectively the circle of radius $\varepsilon'$ around $y$) yields

$$(1) = \det_2(I - \frac{t}{1 + t\sigma^x_\varepsilon}G^{(e)}_{x,x})^\alpha \det_2(I - \frac{s}{1 + s\sigma^{y}_{\varepsilon'}}G^{(e')}_{y,y})^\alpha.$$

$$= \det_2 \left( \begin{array}{cc} I - \frac{t}{1 + t\sigma^x_\varepsilon}G^{(e)}_{x,x} & -\sqrt{\frac{\pi}{\sigma^x_\varepsilon}}r^{(e,e')}_{x,y} \\ -\sqrt{\frac{\pi}{\sigma^y_{\varepsilon'}}}(1 + t\sigma^x_\varepsilon) & I - \frac{s}{1 + s\sigma^{y}_{\varepsilon'}}G^{(e')}_{y,y} \end{array} \right)^{-\alpha}.$$

Note that if, $A$ and $B$ are Hilbert-Schmidt operators, $\det_2(I + A)\det_2(I + B) = e^{-T\tau(AB)}\det_2((I + A)(I + B))$. It follows that if, $A$ and $B'$ are Hilbert-Schmidt operators such that $B'' = (I + A)^{-1}(I + B') - I$ is trace class with zero trace and $AB''$ has also zero trace,

$$\det_2((I + B')^{-1}\det_2(I + B) = \det_2(I + B'') = \det(I + B'')$$

$$= \det((I + A)^{-1}(I + B'))$$

$$= \det((I + A)^{-\frac{1}{2}}(I + B')(I + A)^{-\frac{5}{2}}).$$
Taking now \( A = \left( \begin{array}{cc} \frac{-t}{1+t\sigma_z} & 0 \\ 0 & -\frac{s}{1+s\tau} \end{array} \right) \) and \( B' = \left( \begin{array}{cc} \frac{-t}{1+t\sigma_z} & \sqrt{\frac{s}{1+s\tau}} G^{(e',e')}_{y,x} \\ \sqrt{\frac{s}{1+s\tau}} G^{(e',e')}_{y,x} & \frac{\sqrt{s}}{1+s\tau} \end{array} \right) \) we obtain easily that \( A - B' \) is trace class as \( Tr \left( \left( \begin{array}{cc} 0 & -G^{(e',e')}_{y,x} \\ -G^{(e',e')}_{y,x} & 0 \end{array} \right) \right) \) = 2\( Tr \left( G^{(e',e')}_{y,x} \left( \begin{array}{c} t_{y,x} \\ \epsilon \end{array} \right) \right) \). Therefore, \( B'' = (I + A)^{-1}(B' - A) \) and \( AB'' \) are trace class and it is clear they have zero trace, as both are of the form \( \left( \begin{array}{cc} 0 & S \\ R & 0 \end{array} \right) \).

Therefore, setting \( V = \sqrt{st} (I + t\sigma_z - tG^{(e)}_{x,x} - \frac{s}{1+s\tau} G^{(e',e')}_{y,x} + \frac{s}{1+s\tau} G^{(e',e')}_{y,y}) \left( I + s\sigma_y - sG^{(e')}_{y,y} \right)^{-\frac{1}{2}}, \)

\( (1) = det \left( \begin{array}{cc} I - V & -V \\ -V^* & I \end{array} \right)^{-\alpha}. \)

Hence, \( (1) = det \left( \begin{array}{cc} I - V & -V \\ 0 & I - V^* \end{array} \right)^{-\alpha} = det(I - V^*V)^{-\alpha} = det(I - st(I + s\sigma_y - sG^{(e')}_{y,y} - 1)G^{(e',e')}_{x,x} + \frac{s}{1+s\tau} G^{(e',e')}_{y,x} - 1)G^{(e',e')}_{y,y})^{-\alpha}. \)

This quantity can be expanded. Setting, for any trace class kernel \( K(z, z') \) acting on \( L^2(\pi^y_z) \),

\[ \text{Per}_a(K(n)) = \int \text{Per}_a(K(z_i, z_j), 1 \leq i, j \leq n) \prod_1^n \pi^y_z(dz_i) \]

it equals,

\[ 1 + \sum_{k=1}^{\infty} \frac{1}{k!} \text{Per}_a([stG^{(e',e')}_{y,x} (I + t\sigma_z - tG^{(e)}_{x,x} - 1)G^{(e',e')}_{x,y} (I + s\sigma_y - sG^{(e')}_{y,y} - 1)](k)) = (2) \]

Identifying the coefficients of \( t^k s^l \) in (1) and (2) yields the identity

\[ \mathbb{E}(Q^{(e',e')}_{k}(\langle \tilde{L}_\alpha, \pi^y_z \rangle) Q^{(e',e')}_{l}(\langle \tilde{L}_\alpha, \pi^y_z \rangle)) = \delta_{i,k} \frac{1}{k!} \text{Per}_a([G^{(e',e')}_{y,x} G^{(e',e')}_{x,y}]) + R_{k,l} \]

where \( R_{k,l} \) is the (finite) sum of the \( t^k s^l \) coefficients appearing in

\[ \sum_{k=1}^{\infty} \frac{1}{k!} \text{Per}_a([-stG^{(e',e')}_{y,x} (I + t\sigma_z - tG^{(e)}_{x,x} - 1)G^{(e',e')}_{x,y} (I + s\sigma_y - sG^{(e')}_{y,y} - 1)](k)) \]

different from the term \( \delta_{i,k} \frac{1}{k!} \text{Per}_a([G^{(e',e')}_{y,x} G^{(e',e')}_{x,y}]) \)

The remarkable fact is that the coefficients of \( Q^{(e',e')}_{k} \) are such that this expression involves no term of the form \( Tr([G^{(e)}_{x,x}]^m) \) or \( Tr([G^{(e')}_{y,y}]^m) \). Decomposing the permutations which appear in the expression of the \( \alpha \)-permanent into cycles, we see all the terms are products of traces of operators of the form \( \int G(y_1, y_2) \ldots G(y_n, y_1) \pi^y_{x_1}(dy_1) \ldots \pi^y_{x_n}(dy_n) \) in which at least two \( x_j \)'s are
distinct. It is also clear from the expression (2) above that if we replace \( c^{(c)}_{x,x} \) and \( G^{(ε)}_{y,y} \) by \( σ^ε_I \) and \( σ^ε_II \), the expansion becomes very simple and all terms vanish except for \( l = k \), the term \( \frac{1}{k!} \text{Per}_n((G^{(ε)}_{x,x}G^{(ε')}_y)(l)) \) which will be proved to converge towards \( \alpha^{(α+1)…(α+k−1)}G^{2k}(x,y) = \frac{G^{2k}(x,y)}{k!} \sum_l^n d(k,l)α^l \) (see remark 7 on Stirling numbers).

To prove this convergence, and also that \( R_{k,l} \to 0 \) as \( ε, ε' \to 0 \), it is therefore enough to prove the following:

**Lemma 3.** Consider for any \( x_1, x_2, …, x_n \), \( ε \) small enough and \( ε \leq ε_1, …, ε_n \leq 2ε \), with \( ε_i = ε_j \) if \( x_i = x_j \), an expression of the form:

\[
\Delta = \left| \prod_{i, x_i \neq x_i} G(x_{i-1}, x_i)\left(σ^ε_{x_i}\right)^{m_i} - \int G(y_1, y_2)…G(y_n, y_1)π_{x_1}^ε(dy_1)…π_{x_n}^ε(dy_n) \right|
\]

in which we define \( m_i \) as \( \sup(h, x_{i+h} = x_i) \) and in which at least two \( x_j \)'s are distinct. Then for some positive integer \( N \), and \( C > 0 \), on \( \n \{ ||x_{i−1} − x_i|| \geq \sqrt{ε} \} \)

\[
\Delta \leq C\sqrt{ε} \log(ε)^N
\]

**Proof.** In the integral term, we first replace progressively \( G(y_{i−1}, y_i) \) by \( G(x_{i−1}, x_i) \) whenever \( x_{i−1} \neq x_i \), using triangle, then Schwartz inequalities, to get an upper bound of the absolute value of the difference made by this substitution in terms of a sum \( ∆' \) of expressions of the form

\[
(\int (G(y_1, y_2)−G(x_1, x_2))^2π_{x_1}^ε(dy_1)π_{x_2}^ε(dy_2) \int \prod G^2(y_k, y_{k+1})\prod π_{x_k}^ε(dy_k))^{1/2} \prod G(x_{i, x_{i+1}}).
\]

The expression obtained after these substitutions can be written

\[
W = \prod_{i, x_i \neq x_i} G(x_{i−1}, x_i)\int G(y_1, y_2)…G(y_{m−1}, y_{m})π_{x_1}^ε(dy_1)…π_{x_m}^ε(dy_m)
\]

and we see the integral terms could be replaced by \( (σ^ε_{x_i})^{m_i} \) if \( G \) was translation invariant. But as the distance between \( x \) and \( y \) tends to 0, \( G(x,y) \) is equivalent to \( G_0(x,y) = \frac{1}{π} \log(||x − y||) \) and moreover,

\[
G(x, y) = G_0(x, y) − H^D(x, dz)G_0(z, y).
\]

As our points lie in a compact inside \( D \), it follows that for some constant \( C \), for \( ||y_1 − x|| \leq ε \), \( |\int (G(y_1, y_2)π_{x_2}^ε(dy_2) − σ^ε_{y_2})| < Cε \).
Hence, the difference $\Delta'$ between $W$ and $\prod_{i,x_{i-1}\neq x_i} G(x_{i-1}, x_i) (\sigma_{x_i}^z)^{m_i}$ can be bounded by $\varepsilon W'$, where $W'$ is an expression similar to $W$.

To get a good upper bound on $\Delta$, using the previous observations, by repeated applications of Hölder inequality, it is enough to show that for $\varepsilon$ small enough and $\varepsilon \leq \varepsilon_1, \varepsilon_2 \leq 2\varepsilon$, (with $C$ and $C'$ denoting various constants):

1) $\int (G(y_1, y_2) - G(x_1, x_2)^2 \pi_{x_1} \pi_{x_2} (dy_1 \pi_{x_2}(dy_2)) < C(\varepsilon_1^1 \cdot \|x_1 - x_2\| > \sqrt{\varepsilon} + (G(x_1, x_2)^2 + \log(\varepsilon)^2) \cdot \varepsilon_1 \cdot \|x_1 - x_2\| < \sqrt{\varepsilon}).$

2) $\int G(y_1, y_2)^k \pi_x \pi_y (dy_1 \pi_x (dy_2) < C(\log(\varepsilon))^k$ and more generally

3) $\int G(y_1, y_2)^k \pi_x \pi_y (dy_1 \pi_x (dy_2) < C(\log(\varepsilon))^k.$

As the main contributions come from the singularities of $G$, they follow from the following simple inequalities:

1') $\int \log(\varepsilon^2 + 2R \varepsilon \cos(\theta) + R^2) - \log(R)^2 d\theta$

\[ = \int \log((\varepsilon/R)^2 + 2(\varepsilon/R) \cos(\theta) + 1)^2 d\theta \]

\[ < C((\varepsilon_1 \cdot R > \sqrt{\varepsilon}) + \log^2(\varepsilon/R) \cdot \varepsilon_1 \cdot \|R < \sqrt{\varepsilon}) \]

(considering separately the cases where $\sqrt{\varepsilon/R}$ is large or small)

2') $\int \log(\varepsilon^2(2 + 2 \cos(\theta)))^k d\theta \leq C(\log(\varepsilon))^k$

3') $\int |\log((\varepsilon_1 \cos(\theta_1) + \varepsilon_2 \cos(\theta_2) + r)^2 + (\varepsilon_1 \sin(\theta_1) + \varepsilon_2 \sin(\theta_2))^2)^k d\theta_1 d\theta_2 \leq C(\log(\varepsilon))^k.$

It can be proved by observing that for $r \leq \varepsilon_1 + \varepsilon_2$, we have near the line of singularities (i.e. the values $\theta_1(r)$ and $\theta_2(r)$ for which the expression under the log vanishes) to evaluate an integral which can be bounded (after a change of variable) by an integral of the form $C \int_0^1 (-\log(\varepsilon u))^k d\varepsilon \leq C'(- \log(\varepsilon))^k$ for $\varepsilon$ small enough.

To finish the proof of the theorem, let us note that by the lemma above, and the estimates in its proof, for $\varepsilon \leq \varepsilon_1, \varepsilon_2 \leq 2\varepsilon$, we have, for some integer $N_{i,k}$

\[ |E(Q_k^{\varepsilon_1, \alpha} (\langle \tilde{L}_0, \pi_{x_i} \rangle) Q_k^{\varepsilon_2, \alpha} (\langle \tilde{L}_0, \pi_{x_2} \rangle)) - \delta_{i,k} G(x,y)^{2k} \cdot a_{\alpha + 1} \cdots (\alpha + k - 1) \frac{1}{k!} | \]

\[ \leq C \log(\varepsilon)^{N_{i,k} \cdot (\sqrt{\varepsilon} + G(x,y)^{l+k} \cdot 1_{\|x - y\| < \sqrt{\varepsilon}})} . \quad (10.2) \]

The bound (10.2) is uniform in $(x, y)$ only away from the diagonal as $G(x, y)$ can be arbitrarily large but we conclude from it that for any bounded integrable $f$, $h$,
\[ \left| \mathbb{E}(Q_k^{x,\varepsilon,\alpha}(L_\alpha, \pi^x))Q_l^{x,\varepsilon,\alpha}(L_\alpha, \pi^y)) - \delta_k^l G(x, y)^{2k-1} \right| \lesssim C' \varepsilon \|x-y\|^2 \] (as \( \int G(x, y)^{2k-1} dy \) can be bounded by \( C \varepsilon \), for example).

Taking \( \varepsilon_n = 2^{-n} \), it is then straightforward to check that \( \int f(x)Q_k^{x,\varepsilon,\alpha}(L_\alpha, \pi^x)) dx \) is a Cauchy sequence in \( L^2 \). The theorem follows.

Specializing to \( \alpha = \frac{k}{2} \), \( k \) being any positive integer as before, it follows that Wick powers of \( \sum_{j=1}^k \phi_j^2 \) are associated with self intersection local times of the loops. More precisely, we have:

**Proposition 32.** The renormalized self intersection local times \( \tilde{L}_n \) and the Wick powers \( \frac{1}{2^n n!} : (\sum_{j=1}^n \phi_j^2) \) have the same joint distribution.

**Proof.** The proof is just a calculation of the \( L^2 \)-norm of

\[ \int \left| \frac{1}{2^n n!} \left( \sum_{j=1}^k \phi_j^2 \right)^n : (x) - Q_n \right| f(x) dx \]

which converges to zero with \( \varepsilon \).

The expectation of the square of this difference is the sum of two square expectations which both converge towards \( \frac{k(k+2)(k+2(n-1))}{2^n n!} \int G(x, y)^{2n} f(x) f(y) dy \) and a middle term which converges towards twice the opposite value. The difficult term \( \mathbb{E}((Q_n \phi_j^2 : (\pi^x)) f(x) dx)^2 \) is given by the previous theorem. The two others come from simple Gaussian calculations (note that only highest degree term \( \frac{n^2}{n!} \) of the polynomial \( Q_n \phi_j^2 : (\pi^x) \) contributes to the expectation of the middle term) using identity 5.2.

In the following exercise, we compare the polynomials \( Q_n^{\alpha,\sigma} \) and \( Q_n^{x,\varepsilon,\alpha} \).

**Exercise 42.** (Continuation of exercise 17)

a) Show that \( q_{x,\varepsilon,\alpha}(t, u) = \sum_{l=0}^{\infty} \frac{t^l}{l!} (1 + t \sigma_x^u)^{-l} + \sum_{l=0}^{\infty} \sum_{m=1}^{\infty} \frac{t^l u^{l+m}}{l! m!} (1 + t \sigma_x^u)^{-l-m} \).

b) Deduce that \( Q_N^{x,\varepsilon,\alpha}(u) = \sum_{0 \leq l \leq N} \sum_{k \leq N-l} A_{N,l,k} u^l (\sigma_x)^{N-l-k} \alpha^k \) with \( A_{N,l,k} = \sum_{m=k}^{\infty} (-1)^{N-l-k-m} \frac{(N-1)!}{m!(N-l)!k!(l-m)!} D_{m,k} \) and \( D_{m,k} = \sum C_{m,k} (k, j) 2 \leq j \leq n \) \( \prod (\text{Tr}((G_{x,x}^e)^j))^{k_j} \), for \( k \geq 1 \),

\[ A_{N,l,0} = (-1)^{N-l-k} \frac{(N-1)!}{l!(N-l)!k!(l-m)!} \] and \( A_{N,0,0} = 0 \).

In particular, \( Q_2^{x,\varepsilon,\alpha}(u) = \frac{1}{4} (u^2 - 2 \sigma_x^u - \alpha \text{Tr}((G_{x,x}^e)^2)^2) \) and \( Q_3^{x,\varepsilon,\alpha}(u) = \frac{1}{6} (u^3 - 3 \sigma_x^u u^2 + 6 u^3 \sigma_x^u - 3 \alpha \text{Tr}((G_{x,x}^e)^2)^2 + 6 \alpha \text{Tr}((G_{x,x}^e)^2)^2) \) 3 \alpha \text{Tr}((G_{x,x}^e)^3)^3) \).

**Exercise 43.** Prove that \( \lim_{\varepsilon \to 0} \frac{D_{m,k}}{\sigma_{m,k}} = 1 \)

**Exercise 44.** Show that if we let \( \alpha \) increase, \( q_{x,\varepsilon,\alpha}(t, L_\alpha, \pi^x) \), \( Q_k^{x,\varepsilon,\alpha}(L_\alpha, \pi^x) \) and \( (\tilde{L}_\alpha, f) \) are martingales.
Final remarks:

a) These generalized fields have two fundamental properties:
Firstly they are local fields (or more precisely local functionals of the field $\tilde{L}_\alpha$ in the sense that their values on functions supported in an open set $D$ depend only on the trace of the loops on $D$.
Secondly, note we could have used a conformally covariant regularization to define $\tilde{L}_k^\alpha$, (along the same lines but with slightly different estimates), by taking $\pi_x^\varepsilon$ to be the capacitary measure of the compact set $\{y, G_x^s y \geq - \log \varepsilon\}$ and $\sigma_x^\varepsilon$ its capacity. Then it appears that the action of a conformal transformation $\Theta$ on these fields is given by the $k$-th power of the conformal factor $c = \text{Jacobian}(\Theta)$. More precisely, $\Theta(c^k \tilde{L}_k^\alpha)$ is the renormalized $k$-th power of the occupation field in $\Theta(D)$.

b) It should be possible to derive from the above remark and from hyper-contractive type estimates the existence of exponential moments and introduce non trivial local interactions as in the constructive field theory derived from the free field (Cf [50]).

c) Let us also briefly consider currents. We will restrict our attention to the one and two dimensional Brownian case, $X$ being an open subset of the line or plane. Currents can be defined by vector fields, with compact support. Then, if we now denote by $\phi$ the complex valued free field (its real and imaginary parts being two independent copies of the free field), $\int_I \omega$ and $\int_X (\overline{\phi} \partial_x \omega - \phi \partial_x \overline{\omega}) dx$ are well defined square integrable variables in dimension 1 (it can be checked easily by Fourier series). The distribution of the occupation field of the loop process "twisted" by the complex exponential $\exp(\sum_{l \in L} i \omega + \frac{1}{2} \hat{l}(\|\omega\|^2))$ appears to be the same as the distribution of the field $\overline{\phi} \overline{\omega}$ "twisted" by the complex exponential $\exp(\int_X (\overline{\phi} \partial_x \omega - \phi \partial_x \overline{\omega}) dx)$ (Cf [26]).
In dimension 2, logarithmic divergences occur.

d) There is a lot of related investigations. The extension of the properties proved here in the finite framework has still to be completed, though the relation with spanning trees should follow from the remarkable results obtained on SLE processes, especially [22]. Note finally that other essential relations between SLE processes, loops and free fields appear in [59], [42], [7], and more recently in [45] and [46].
