Introduction to False Discovery Rate

- Introduced by Benjamini and Hochberg (1995).
- False Discovery Proportion (FDP): How many False Discoveries made among all discoveries?
- False Discovery Rate (FDR): the expected value of FDP.

Source: stats.stackexchange.com

Problem settings

- $\mathbf{X} \in \mathbb{R}^{n imes p}$, $\mathbf{y} \in \mathbb{R}^n$. Example: \mathbf{X} is MRI data, \mathbf{y} outcome.
- Linear model assumption $\mathbf{y} = \mathbf{X}\boldsymbol{\beta}^* + \sigma\boldsymbol{\epsilon}$ with $\epsilon_i \sim \mathcal{N}(0,1)$.
- Support set $S := \{i : \beta_i^* \neq 0\}$ and its estimate \hat{S} .

False Discovery Proportion – FDP

$$\mathsf{FDP} = \frac{\mathbf{card}(\hat{\mathcal{S}} \cap \mathcal{S}^c)}{\mathbf{card}(\hat{\mathcal{S}}) \lor 1}$$

False Discovery Rate – FDR

$$\mathsf{FDR} = \mathbb{E}[\mathsf{FDP}]$$

Multivariate Statistical Inference

n > p: Ordinary Least Square (OLS)

$$\hat{oldsymbol{eta}}^{OLS} = \operatorname*{argmin}_{oldsymbol{eta} \in \mathbb{R}^p} rac{1}{2} \left\| \mathbf{y} - \mathbf{X} oldsymbol{eta}
ight\|_2^2$$

 $\longrightarrow \hat{oldsymbol{eta}}^{OLS} = (\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X}^T \mathbf{y} \rightarrow$ test score, p-value, confidence interval.

n < p: No closed form solution – $\mathbf{X}^T \mathbf{X}$ not invertible

Solution: : Lasso, Ridge, Elastic Net \rightarrow p-value, confidence interval for variable selection?

 \longrightarrow Knockoff Inference: Multivariate Variable Selection for High-dimensional settings.

Knockoff Variables: Definition

Definition (?)

$$\begin{split} \tilde{\mathbf{X}} &= (\mathbf{x}_1, \dots, \mathbf{x}_p) \text{ is model-X knockoffs of } \mathbf{X} = (\mathbf{x}_1, \dots, \mathbf{x}_p) \text{ if and only if:} \\ \bullet \forall \text{ subset } \mathcal{K} \subset \{1, \dots, p\}: \ (\mathbf{X}, \tilde{\mathbf{X}})_{\mathsf{swap}(\mathcal{K})} \stackrel{d}{=} (\mathbf{X}, \tilde{\mathbf{X}}) \\ \bullet \quad \tilde{\mathbf{X}} \perp \mathbf{y} \mid \mathbf{X} \end{split}$$

Tuan-Binh Nguyen

Aggregation of Multiple Knockoffs

- \tilde{X} is **noisy copies** of original variables X:
 - Share same 'structure' with original design matrix, but
 - Has to be null variables.

Knockoff Sampling: Second-order Knockoffs

Shares the same first 2 moments - mean and covariance:

 $\mathbb{E}[\tilde{\mathbf{X}}] = \mathbb{E}[\mathbf{X}] = \boldsymbol{\mu}, \quad \mathbb{E}[\tilde{\mathbf{X}}^T \tilde{\mathbf{X}}] = \boldsymbol{\Sigma} \quad \text{and} \quad \mathbb{E}[\tilde{\mathbf{X}}^T \mathbf{X}] = \boldsymbol{\Sigma} - \text{diag}\{\mathbf{s}\}$

▲□▶ ▲□▶ ▲三▶ ▲三▶ - 三 - のへで

Knockoff Sampling: Second-order Knockoffs

 diag{s} is perturbation matrix that makes the joint covariance cov(X, X̃) matrix positive definite:
 → Equi-correlated formula: s_j = 2λ_{min}(Σ) ∧ 1 (Candès et al.,

2018)

• In practice: Estimation of Σ is required.

Assumption

$$(X_{i1}, \ldots X_{ip}, y_i) \stackrel{i.i.d}{\sim} F_{XY}, \forall i = 1, \ldots, n$$
, and F_X is known.

Assumption: \mathbf{X} has Gaussian design

$$\tilde{\mathbf{x}_j} \mid \mathbf{x}_j \sim \mathcal{N}(\boldsymbol{\mu}, \mathbf{V})$$

$$\mathbf{V} = 2 \operatorname{diag}\{\mathbf{s}\} - \operatorname{diag}\{\mathbf{s}\} \boldsymbol{\Sigma}^{-1} \operatorname{diag}\{\mathbf{s}\}$$

ヘロト 人間ト 人団ト 人団ト

Knockoff Statistic

Definition (Candès et al. (2018))

A knockoff statistic $\mathbf{W} = \{W_j\}_{j \in [p]}$ is a measure of feature importance that satisfies the two following properties:

 $\textbf{0} \quad \text{Depends only on } \mathbf{X}, \mathbf{\tilde{X}} \text{ and } \mathbf{y}$

$$\mathbf{W} = f(\mathbf{X}, \mathbf{X}, \mathbf{y})$$
, and

Swapping the original variable column x_j and its knockoff column x̃_j will switch the sign of W_j iff j is in the support set S:

$$W_j([\mathbf{X}, \tilde{\mathbf{X}}]_{swap(S)}, y) = \begin{cases} W_j([\mathbf{X}, \tilde{\mathbf{X}}], \mathbf{y}) \text{ if } j \in \mathcal{S}^c \\ -W_j([\mathbf{X}, \tilde{\mathbf{X}}], y) \text{ if } j \in \mathcal{S} \end{cases}$$

・ロト ・ 同ト ・ ヨト ・ ヨト

Assumption (Null Distribution of Knockoff Statistic)

Under the Null hypothesis, the Knockoff Statistics defined above, i.e. $\{W_j\}_{j \in S^c}$, follow the same distribution.

Remark

From Barber and Candès (2015): this Null distribution is symmetric around 0.

▲ □ ▶ ▲ □ ▶ ▲ □ ▶

Knockoff Inference (Barber and Candès, 2015)

Step 1

Construct knockoff variables, concatenate $[\mathbf{X}, \mathbf{ ilde{X}}] \in \mathbb{R}^{n imes 2p}$

Step 2

Calculate knockoff test-statistics: Lasso coefficient-difference, obtain

$$\hat{\boldsymbol{eta}} = \min_{\mathbf{w} \in \mathbb{R}^{2p}} \frac{1}{2} \|\mathbf{y} - [\mathbf{X}, \tilde{\mathbf{X}}]\boldsymbol{eta}\|_2^2 + \lambda \|\boldsymbol{eta}\|_1$$

then take the difference: $W_j = \left|\hat{\beta}_j(\lambda)\right| - \left|\hat{\beta}_{j+p}(\lambda)\right|$ for each j

イロト イヨト イヨト 一座

Knockoff Inference (Barber and Candès, 2015)

Step 3 – FDR controlling threshold

For given t > 0, False Discoveries Proportion can be estimated as:

$$\widehat{\mathsf{FDP}}(t) = \frac{1 + \#\{j : W_j \le -t\}}{\#\{j : W_j \ge t\}}$$

then, for FDR level $\alpha \in (0,1),$ calculate the threshold $\tau > 0$

$$\tau = \min\left\{t > 0 : \widehat{\mathsf{FDP}}(t) \le \alpha\right\}$$

Step 4

Select the variables:
$$\hat{S}(\tau) = \{j: W_j \ge \tau \mid j = 1, \dots, p\}$$

Knockoff Inference: Theoretical Guarantee FDR control

Theorem (Barber and Candès, 2015; Candès et al., 2018) $\mathsf{FDR}(\tau) = \mathbb{E}\left[\frac{\mathbf{card}(\hat{S}(\tau) \cap \mathcal{S}^c)}{\mathbf{card}(\hat{S}(\tau)) \lor 1}\right] \le \alpha$

Proof: Using martingale theory (optional stopping time theorem).

Instability of knockoff procedure

Settings for Simple Scenario Simulation: 3 simulation parameters: ρ , snr and sparsity.

•
$$n = 500$$
 , $p = 1000$.

• $\mathbf{X} \sim \mathcal{N}(\mathbf{0}, \boldsymbol{\Sigma})$ symmetric Toeplitz matrix.

•
$$\rho \in [0,1) : \Sigma = \begin{bmatrix} \rho^{0} & \rho^{1} & \rho^{2} & \dots & \rho^{p-1} \\ \rho^{1} & \rho^{0} & \rho^{1} & \dots & \rho^{p-2} \\ \vdots & \dots & \ddots & \dots & \vdots \\ \rho^{p-2} & \rho^{p-3} & \dots & \rho^{0} & \rho^{1} \\ \rho^{p-1} & \rho^{p-2} & \rho^{p-3} & \dots & \rho^{0} \end{bmatrix}$$

• $\mathbf{y} = \mathbf{X}\boldsymbol{\beta}^{*} + \sigma\boldsymbol{\epsilon}, \ \boldsymbol{\epsilon}_{i} \sim \mathcal{N}(0,1).$
• $\sigma = \frac{\|\mathbf{X}\boldsymbol{\beta}^{*}\|_{2}}{\operatorname{snr} \times \|\boldsymbol{\epsilon}\|_{2}}$
• sparsity $= \frac{\operatorname{card}(\mathcal{S})}{p} \in [0,1]$

Instability of knockoff procedure

Figure: 100 runs of knockoff inference on the <u>same simulation</u> n=500, p=1000, snr=3.0, $\rho = 0.7$, sparsity = 0.06

Solution: Knockoffs Statistic conversion

Introduce the intermediate p-values: convert Knockoff statistic W_j to π_j :

$$\pi_j = \begin{cases} \frac{1 + \#\{k : W_k \le -W_j\}}{p} & \text{if } W_j > 0\\ 1 & \text{if } W_j \le 0 \end{cases}$$

Tuan-Binh Nguyen

Aggregation of Multiple Knockoffs

June 03, 2020

< □ > < □ > < □ > < □ > < □ > < □ >

Solution: Knockoffs Statistic conversion

Introduce the intermediate p-values: convert Knockoff statistic W_j to π_j :

$$\pi_j = \begin{cases} \frac{1 + \#\{k : W_k \le -W_j\}}{p} & \text{if } W_j > 0\\ 1 & \text{if } W_j \le 0 \end{cases}$$

Tuan-Binh Nguyen

Aggregation of Multiple Knockoffs

Step 1: For $b = 1, 2, \dots, B$ the number of bootstraps:

- Run knockoff sampling, calculate test statistic $\left\{ W_{j}^{(b)}
 ight\}_{j \in [p]}$
- Convert the test statistic $W_j^{(b)}$ to $\pi_j^{(b)}$:

$$\pi_j^{(b)} = \begin{cases} \frac{1 + \#\{k : W_k^{(b)} \le -W_j^{(b)}\}}{p} & \text{if } W_j^{(b)} > 0\\ 1 & \text{if } W_j \le 0 \end{cases}$$

イロト イヨト イヨト ・

Step 2 – Quantile Aggregation of p-values (Meinshausen et al., 2009)

$$\bar{\pi}_j = \min\left\{\frac{q_\gamma(\pi_j^{(b)})}{\gamma}, 1\right\} \quad \forall j \in [p]$$

For $\gamma \in (0,1)$ with $q_{\gamma}(\cdot)$ the empirical $\gamma\text{-quantile function}.$

Tuan-Binh Nguyen

Aggregation of Multiple Knockoffs

Step 3 – FDR control with $\bar{\pi}$

- Order $\bar{\pi}_j$ ascendingly: $\bar{\pi}_{(1)} < \bar{\pi}_{(2)} \cdots < \bar{\pi}_{(p)}$
- Given FDR control level $\alpha \in (0,1)$, find largest k such that:
 - $\bar{\pi}_{(k)} \leq k \alpha / p$ (Benjamini and Hochberg, 1995), or
 - $\bar{\pi}_{(k)} \leq \frac{k\alpha}{p\sum_{i=1}^{p} 1/i}$ (Benjamini and Yekutieli, 2001)

 \longrightarrow FDR threshold: $\tau = \bar{\pi}_{(k)}$

• $\hat{\mathcal{S}}_{AKO} = \{j : \bar{\pi}_j \leq \tau \mid j \in [p]\}$

Assumption (Null Distribution of Knockoff Statistic)

Under the Null hypothesis, the Knockoff Statistics defined above, i.e. $\{W_j\}_{j \in S^c}$, follow the same distribution.

Lemma (Non-asymtotical validity of Intermediate p-Values)

Under the above assumption , and furthermore assume $|S^c| \ge 2$, the empirical p-value π_j satisfies

$$\forall t \in (0,1), \mathbb{P}(\pi_j \le t) \le \frac{\kappa p}{|\mathcal{S}^c|} t$$

for all $j \in S^c = \{j = 1, \dots, p : \beta_j^* = 0\}$ and where $\kappa = \frac{\sqrt{22} - 2}{7\sqrt{22} - 32} \le 3.24$

▲□▶ ▲圖▶ ▲国▶ ▲国▶ ▲国 ● のへ⊙

Theorem (Non-asymtotic guarantee for FDR control with AKO)

If the above assumption holds, and if $|S^c| \ge 2$, then for an arbitrary number of bootstraps B, the output \hat{S}_{AKO} of Aggregation of Multiple Knockoff (AKO) controls FDR under predefined level $\alpha \in (0,1)$ in asymptotic regime:

$$\mathbb{E}\left[\frac{|\hat{\mathcal{S}}_{AKO} \cap \mathcal{S}^c|}{|\hat{\mathcal{S}}_{AKO}| \lor 1}\right] \le \kappa \alpha$$

where
$$\kappa = \frac{\sqrt{22-2}}{7\sqrt{22}-32} \le 3.24.$$

Same settings: Simple Scenario with

- n = 500, p = 1000.
- $\mathbf{X} \sim \mathcal{N}(\mathbf{0}, \boldsymbol{\Sigma})$
- $\mathbf{y} = \mathbf{X} \boldsymbol{\beta}^* + \sigma \boldsymbol{\epsilon}, \ \epsilon_i \sim \mathcal{N}(0, 1)$. with $\boldsymbol{\Sigma}$ symmetric Toeplitz matrix.
- 3 simulation parameters: ρ , snr and sparsity.

Experimental Results - Synthetic Data

Figure: Histogram of FDP & Power for 100 runs of Original Knockoff (top) vs. Aggregated Knockoff (bottom) under the same simulation. $SNR = 3.0, \rho = 0.5, \text{ sparsity} = 0.06.$

Aggregation of Multiple Knockoffs

Empirical Analysis for the choice of B and γ

Figure: FDR and Averaging Power for 30 simulations with fixed SNR = $3.0, \rho = 0.7$, sparsity = 0.06 while varying B and γ

- Vary each of the three simulation parameters while keeping the others unchanged at default value: SNR = $3.0, \rho = 0.5$, sparsity = 0.06
- Benchmarking methods:
 - Aggregation of Multiple Knockoffs (AKO)
 - Vanilla Knockoff (KO) (Candès et al., 2018)
 - Debiased Lasso (DL-BH) (Javanmard and Javadi, 2019)
 - Simultaneous Knockoff (KO-GZ) (Gimenez and Zou, 2019)

Conclusion:

- Knockoff:
 - Versatile (different loss functions, different test statistics)
 - But unstable, depends on quality of knockoff variables.
- Aggregation of Multiple Knockoffs
 - \longrightarrow increases stability
 - \longrightarrow theoretically control FDR
 - \longrightarrow higher power

▲ □ ▶ ▲ □ ▶ ▲ □ ▶

Future work:

- Knockoff Sampling Scheme for scaling to very large dimension: promising methods include Deep Knockoffs Machine (Romano et al., 2018) – Generative adversarial knockoff networks (Jordon and Yoon, 2019)
- Further analysis on Theoretical Properties of AKO: relax assumptions about knockoff statistics
